

A Note on α -stable and α -inverse Gaussian Laws

Abstract

In this article we obtain the first passage time distribution of α -stable Lévy processes. We derive the moment estimators of the parameters of α -inverse Gaussian laws and also their asymptotic distribution.

Key Words: asymptotic normality, Brownian motion, estimator, first passage time, inverse Gaussian, Laplace transform, stable.

1 Introduction

α -stable laws are infinitely divisible and hence one can define corresponding α -stable Lévy processes (α -SLP). The range of α is $0 < \alpha \leq 2$ and for $\alpha = 2$ the α -stable law is Gaussian/ normal law and the corresponding α -SLP is the Brownian motion process (BMP). It is known that $\alpha = 1$

$\alpha = 2$ -stable law is the first

passage time (FPT) distribution of BMP with zero drift (Feller, 1971, p.174)

and for a BMP with positive drift, the FPT distribution is inverse Gaussian

(IG), Johnson and Kotz (1970, p.137). IG laws were generalized to α -IG (α -IG) laws in Pillai and Satheesh (1992).

Here, in section 2, we obtain the FPT distribution of α -SLP. Since the density of α -IG laws is not in closed form we derive the moment estimators of its parameters and obtain their asymptotic distribution in section 3. Another possible approach based on the p.d.f. of Gamma is also sketched.

1

2 α -stable and α -inverse Gaussian

2 FPT distribution of α -SLP

We need the following result from Eaton et al. (1971) to define the α -SLP.

They call it extreme stable since the parameter α in the stable model is set as $\alpha = 1$. They have taken the location parameter also as zero. However, here we refer to them as α -stable laws.

Theorem 2.1. The function $M(s) = \exp\{-b(1-\alpha)|s|^\alpha\}$; $0 < \alpha \leq 2$; $0 < \text{Re}(s) < 1$; $0 < b < \infty$; $b > 0$ are moment generating functions (MGF) of α -stable laws.

Definition 2.2. Lévy processes $X(t)$; $t \geq 0$ are α -SLP, if the distribution of $X(1)$ is α -stable with MGF $M(s) = \exp\{-b(1-\alpha)|s|^\alpha\}$.

FPT distributions of processes are important as they give the distribution of the time taken for the process to reach/ cross a barrier. If $a > 0$ is the barrier, then the random variable (r.v.) $T(a) = T = \inf\{t > 0 : X(t) = a\}$ denote the FPT of $X(t)$. Here $t > 0$, since $X(0) = 0$ for a Lévy process. Since the location parameter is zero for the α -stable laws considered here, the α -SLP has zero drift. Further, for $1 < \alpha \leq 2$, it has finite mean and hence martingale based arguments on $X(t)$ are justified. We now derive the FPT distribution of α -SLP using standard arguments based on optional sampling theorem (see, Karlin and Taylor, 1975) applied to the martingale of $X(t)$ in proposition 2.3. Other relevant literature are: Novikov (1981, 2009), Alili and Kyprianov (2005), Schilling and Partzsch (2014), Vellaisamy and Kumar (2017).

Proposition 2.3. For the α -SLP $X(v)$; $v \geq 0$, $W(v) = \exp\{-b(1-\alpha)|X(v)|^\alpha\}$,

$s > 0$ a constant, is a martingale, where $\beta = b(\beta - 1)s$.

Proof. Since, E

\square

$$e^{sX(t)}$$

$$= e_{-t}, E(jW(v)) = E(W(v)) = e_{-v}E$$

\square

$$e^{sX(v)}$$

$$= 1 <$$

1. Since Levy processes have stationary and independent increments, for $u < v$, $X(v) - X(u)$ is independent of \mathcal{F}_u , the filtration up to time u . Now, $E(W(v) | \mathcal{F}_u) = E(\exp(s(X(v) - X(u))) | \mathcal{F}_u)$

$$= e_{-v}E$$

\square

$$e^{s(X(v) - X(u)) + sX(u)} = \mathcal{F}_u$$

$$= e_{-v}E$$

\square

$$e^{s(X(v) - X(u))} = \mathcal{F}_u$$

\square

E

\square

$$e^{sX(u)} = \mathcal{F}_u$$

\square

$$= e_{-v}E$$

\square

$$e^{sX(v-u)} = \mathcal{F}_u$$

\square

$$e^{sX(u)} = e_{-v}e_{-(v-u)}e^{sX(u)} = e^{sX(u)} \square_u = W(u);$$

Satheesh 3

and that completes the proof.

Theorem 2.4. The FPT distribution of β -SLP for $1 < \beta < 2$, is $1/\beta$ -stable.

Proof. Let the r.v. $T(\beta) = T$ denote the FPT for the β -SLP $fX(t); t \geq 0$ to reach or cross $\beta > 0$. We know that for $fX(t)g$, $W(t) = \exp(sX(t) - \beta t)$ is a martingale, where $\beta = b(\beta - 1)s$. For a martingale $fW(t)g$ and for the FPT T (which is a stopping time), $EfW(0)g = EfW(T \wedge t)g$. As $X(0) = 0$, $W(0) = 1$ and hence $EfW(T \wedge t)g = 1$. That is,

$$E[\exp(sX(T \wedge t) - \beta(T \wedge t))] = 1; \quad (1)$$

Note that $\beta = b(\beta - 1)s > 0$ for $1 < \beta < 2$ and so $0 \leq W(T \wedge t) \leq e_{-t}$:

Now assuming $PfT < 1g = 1$ (we will justify this at the end of the proof) we may pass to the limit as $t \rightarrow \infty$ under the expectation in (1) by the optional sampling theorem, yielding;

$$1 = \lim$$

$t \rightarrow \infty$

$$E [expfsX(T ^ t) \square _ (T ^ t)g] = e_{s_}E$$

$$e_{\square_T _}$$

:

Thus; E

$$e_{\square_T _}$$

$$= e_{\square s_}:$$

Since $_ = b(_ \square 1)s_ =$ s =

n

$$\bar{b}(_ \square 1)$$

$$01=_$$

, we get the LT of the FPT as,

E

$$e_{\square_T _}$$

$$= e$$

$$\frac{_}{[b(_ \square 1)]^{1=_}}$$

$$_1=_$$

;

;

which is that of $_1$

$_1$ -stable law (Feller, 1971, p.448).

Finally, since $PfT < 1g = \lim_{\#0} E$

$$e_{\square_T}$$

= 1; T has a proper distribu-

tion, justifying our assumption $PfT < 1g = 1$.

Remark 2.1. E

$$e_{\square_T}$$

= $e_{\square_1=_}$ is the LT of a probability distribution only

when $_1=_$ has completely monotone derivative. That is, if $0 < 1=_ < 1 =)$

$_ > 1$ (Feller 1971, p.448). Also, here we need $_ > 0$. These are the reasons

for restricting the range of $_$ to $1 < _ \leq 2$ in the above theorem. When $_ = 1$

the distribution is degenerate.

Remark 2.2. One may note that when $_ = 2$, the $_SLP$ is BMP and the LT

of T is E

$$e_{\square_T}$$

$$= e$$

h

$\square p_$

b

i

$\alpha_1 = 2$

which is that of α_1

α_2 -stable, as is known.

α_4 -stable and α_4 -inverse Gaussian

3 Estimation of Parameters of α -IG

By Pillai and Satheesh (1992), a r.v. $X \sim \alpha$ -IG(α ; β ; m) (α -IG), if its LT is;

$$L(s) = \exp$$

m

α

$$[1 - (1 +$$

$\frac{2\beta}{\alpha}$

m

$s)^\alpha]^{-m}$; $s \geq 0$; $0 < \alpha < 1$; $\beta > 0$; $m > 0$:

The probability density function (p.d.f.) of $X \sim \alpha$ -IG(α ; β ; m) is;

$$f(x) =$$

$\frac{1}{c}$

\exp

$-\frac{x}{c}$

$-\frac{m}{x}$

$-\frac{1}{x}$

$-\frac{1}{x}$

$-\frac{1}{x}$

$$\frac{_2}{2} \frac{_1_3 - _22}{(2_22 - \frac{_1_3}{2})^2} :$$

Let x_1, \dots, x_n be a simple random sample of size n from $X \sim IG(\alpha; \beta; m)$ and a, b, c respectively denote the mean, variance and third central moment from the sample. Now the moment estimators of the parameters $\alpha; \beta$ and m are;

$$\hat{\alpha} = \frac{2b^2 - ac}{b^2 - ac}$$

$$;$$

$$\hat{\alpha} = \frac{a}{2_2}$$

$$= \frac{a}{2}$$

$$\frac{b^2 - ac}{2b^2 - ac}$$

and

$$\hat{m} = \frac{2a}{b}$$

$$(1 - \frac{_2}{_3})_2 = \frac{a^3 b}{2 ac - b^2}$$

$$(2b^2 - ac)^2 :$$

Remark 3.1. From remark 5 in Pillai and Satheesh (1992), $\text{Gamma}(\alpha, 2/\beta)$ law is the mixture of $X \sim IG(\alpha; \beta; \alpha^2)$ with $\beta \sim \text{Exp}(\beta)$. The corresponding stochastic representation is $Y = XE$. This opens up the possibility of transforming the observations on IG r.v. X to the corresponding gamma r.v. Y , estimating the parameters of the gamma and in turn that of the IG . Comparing these estimates with the moment estimates obtained above for their efficiency and closeness is worth investigating. This demands simulation studies and will be reported elsewhere.

3.1 Asymptotic distribution of the estimators

If $X \sim IG(\underline{\mu}; \underline{\nu}; m)$, then the vector $(X_1; X_2; X_3)$ has mean $\underline{\mu} = (\mu_1; \mu_2; \mu_3)$ and covariance matrix

$$\underline{\Sigma} = \begin{pmatrix} \frac{\mu_2}{2} & & \\ \frac{\mu_3}{4} & \frac{\mu_2}{2} & \\ \frac{\mu_3}{6} & \frac{\mu_2}{4} & \frac{\mu_2}{3} \end{pmatrix}$$

where $\mu_k = E$

$$\frac{1}{X_k}$$

; $k = 1; 2; \dots; 6$. Define \underline{X}

$$j = 1$$

n

$$P_n$$

$$i=1 X_j$$

; $j = 1; 2; 3$ and

6 μ -stable and μ -inverse Gaussian

put \underline{X}

$$= (\underline{X}$$

$$1; \underline{X}$$

$$2; \underline{X}$$

3). Then, by the multivariate CLT (Rao, 1973, p.128),

p

$$n(\underline{X}$$

$$\frac{1}{n} \sum_{i=1}^n \underline{X}_i)$$

$\xrightarrow{d} N_3(0; \underline{\Sigma})$:

Using the relations between \underline{g}_i and \underline{g}_i (Rao, 1973, p.101), define the following functions g_i , so that we get $g_i(\underline{X}$

); $i = 1; 2; 3$, the corresponding moment estimators.

$$g_1(\underline{\mu}) = g_1(\mu_1; \mu_2; \mu_3) = \mu_1 = 1 +$$

$$\frac{\mu_2}{2}$$

$$+ \frac{1}{2}$$

$$\frac{\mu_2}{4}$$

$$+ \frac{1}{2} \mu_1 (\frac{\mu_3}{3} + 3\mu_1\mu_2 + 2\mu_2$$

$$+ \frac{1}{3})$$

;

$$g_2(\underline{\mu}) = g_2(\mu_1; \mu_2; \mu_3) = \mu_2 =$$

$$\frac{\mu_2}{2}$$

2_

where G = @g(_)

@_j

Pillai and Satheesh (1992) showed that IG laws are self-decomposable. This motivated Abraham and Balakrishna (1999) to develop AR(1) models with IG marginals. Sri Ranganath and Balakrishna (2019) discussed Bayesian analysis of IG stochastic conditional duration models. Vellaisamy and Kumar (2017) derived the FPT distribution of IG process. These suggest the possibility of discussing IG laws in other modelling contexts.

Summary In this paper the FPT distribution of SLP, for 1 < _ _ 2, is obtained as

_ -stable law. Moment estimators of the parameters of IG law are derived and they are shown to be jointly asymptotically normal.
