

Long term effect of different nutrient management practices on micronutrient uptake under rice-rice cropping system

ABSTRACT

A field experiment entitled "Carbon sequestration and soil health under long term soil fertility management in rice-rice cropping system" was carried out under field conditions during both *kharif* and *rabi* seasons of 2016-2017 and 2017- 2018 at Andhra Pradesh Rice Research Institute and Regional Agricultural Research Station, Maruteru, West Godavari district in the ongoing All India Coordinated Research Project on Long Term Fertilizer Experiment Project. The results reported that the data regarding influence of long-term use of inorganics, organics and their combination on micronutrient uptake at different growth stages in *kharif* and *rabi* during both the years of the study indicated that there was significantly increase with application of 100% RDF in combination with ZnSO₄ and FYM @ 5t ha⁻¹. However, it was on par with that of application of 100 % RDF along with ZnSO₄ @ 40 kg ha⁻¹ and significantly superior over other treatments. The application of 50 % NPK + 50 % N through FYM was on par with 100 % RDF. Application of 100 % RDF along with ZnSO₄ @ 40 kg ha⁻¹ and application of 100 % NPK though not differ significantly and on par with each other during four seasons of study.

Key words: organic manures, Zn uptake, micronutrient uptake and bio-fertilizers

Rice (*Oryza sativa* L.) is the principal food crop of the world, contributes to about 60% of the world's food. Rice is the major cereal crop feeding two- third of the global population. Rice occupies one-third of the world's crop land planted to cereals and provides 30-60% of the calories consumed by nearly three billion people (Gurra *et al.*, 1998). Rice production is an important part of Asia's economy.

Comment [AB1]: The keywords are traditionally written in alphabetical order separated by semicolons. The author(s) may please take a note of it.

Comment [AB2]: INTRODUCTION

*This paper is a part of the author's Ph.D. (Ag.) thesis entitled "Carbon sequestration and soil health under long term soil fertility management in rice-rice cropping system", submitted to Acharya N.G. Ranga Agricultural University, Lam, Guntur.

Comment [AB3]: No need to write this part in a research article.

Continuous use of high level of chemical fertilizers had leadto soil degradation problems, which also proved detrimentalto soil health. Long-term fertilizer experiments conducted all over India showed, on an average, that rice removed 20.7 kg N, 5.17 kg P and 35.5 kg K during wet season for every ton of grain yield (Yoshida, 1981). It is therefore, necessary to apply fertilizer elements particularly N, P and K either through organic or through inorganic sources in optimal quantity to improve and sustain the productivity.

A large number of experiments (Sharma *et al.*, 2008) at research stations and on farmers field have demonstrated the importance of organic manures, farmyard manure and bio - fertilizers supplementing the nutrient requirements of crop and providing yield stability. Farming systems and the best management practices that hold promise for sequestering soil organic carbon, potential to enhance agricultural sustenance, reduce negative environment impacts of anthropogenic CO₂ emissions need to be identified and thoroughly investigated.

MATERIALS AND METHODS

A long-term field experiment was initiated in *kharif*, 1989 with rice-rice cropping system at APRRI & RARS, Maruteru, West Godavari. The experiment was carried out under field conditions during *kharif* and *rabi* seasons of 2016-2017 and 2017- 2018 at Andhra Pradesh Rice Research Institute and Regional Agricultural Research Station, Maruteru, West Godavari district in the ongoing All India Coordinated Research Project on Long Term Fertilizer Experiment Project. The treatments consisted of control, 100 per cent recommended dose of NPK, 100 per cent recommended dose of NK, 100 per cent recommended dose of PK, 100 per cent recommended dose of NP, 100 per cent recommended dose of NPK+ZnSO₄ @ 40 kg/ ha, 100 per cent recommended dose of NPK+ZnSO₄ @ 40 kg/ ha+ FYM @ 5 t ha⁻¹, 50 per cent recommended dose of NPK, 50 % NPK + 50 % N through green manures, 50 % NPK + 50 % N through FYM, 50 % NPK + 25 % N through green manures + 25 % N through FYM and FYM only @ 10 t/ha. There were twelve treatments laidout in RBD with three replications for both *kharif* and *rabi* seasons in two years of study. Nitrogen was applied through urea in three equal

Comment [AB4]: The current experiment

Comment [AB5]: The Longitude and Latitude of the study areas should be mentioned

splits (1/3rd basal+1/3rdat tillering+1/3rdat panicle initiation stage). Phosphorus was applied through DAP was used duly taking its N content into account and potassium as muriate of potash (60 % K₂O) and zinc as zinc sulphate (ZnSO₄.7H₂O). The entire dose of phosphorus, potassium and zinc were applied as basal. Recommended dose of fertilizer for *kharif* season was 90: 60: 60 N: P₂O₅: K₂O kg ha⁻¹ and for *rabi* season it was 180: 90: 60 N: P₂O₅: K₂O kg ha⁻¹. Well decomposed farmyard manure (FYM) manure and *Calotropis* (green leaf manure) were applied two weeks before transplanting. The experiment on rice – rice sequence as detailed above was repeated on a same site during *kharif* 2016-17 and *rabi* 2017-18, respectively. Popular cultivars of *kharif* rice and *rabi* rice, MTU-1061, MTU-1010 respectively, were used for the study. The uptake of nutrients at harvest was worked out by using the following formulae. Macronutrients uptake was expressed as kg ha⁻¹ and micronutrient uptake was expressed in g ha⁻¹.

$$\text{Macronutrient Uptake (kg ha}^{-1}\text{)} = \frac{\text{Nutrient concentration (\%)} \times \text{Drymatter yield (kg ha}^{-1}\text{)}}{100}$$

$$\text{Micronutrient Uptake (g ha}^{-1}\text{)} = \frac{\text{Nutrient concentration (\%)} \times \text{Drymatter yield (kg ha}^{-1}\text{)}}{1000}$$

RESULTS AND DISCUSSION

Iron uptake

The iron uptake data at tillering, panicle initiation and at harvest stage were statistically computed at all stages in all the four seasons iron uptake was significantly influenced by different treatments.

At tillering stage the maximum iron uptake (1.57, 2.73, 1.96, 2.84 kg ha⁻¹) was recorded in the treatment T₇, which was significantly superior over all other treatments. The lowest iron uptake (0.49, 0.65, 0.52, 0.66 kg ha⁻¹) was recorded in the treatment T₁ (control). Similar results were observed in *kharif*, *rabi* during both the years of study.

At panicle initiation stage the maximum iron uptake (4.18, 4.83, 4.25, 4.68 kg ha⁻¹ in *kharif*, *rabi*, 2016-17 and 2017-18, respectively) was recorded in the treatment T₇, which was significantly superior over all other treatments. The lowest iron uptake (0.49, 0.65, 0.52, 0.66 kg

ha⁻¹) was recorded in the treatment T₁ (control). Similar results were observed in *kharif*, *rabi* during both the years of study.

The highest iron accumulation in grain was observed in T₇ (100% RDF+ZnSO₄+FYM @ 5 t ha⁻¹) which was significantly superior over all other treatments in *kharif*, *rabi* during both the years of study. As expected, untreated control (T₁) registered the lowest iron uptake (0.37, 0.48, 0.37, 0.48 kg ha⁻¹ in *kharif*, *rabi*, 2016-17 and 2017-18, respectively). The lowest K uptake in control plot by the crops is due to the lower yield obtained in these plots.

The iron uptake by straw was ranged from 1.02 to 3.29; 1.45 to 4.15; 1.03 to 3.41; 1.42 to 4.21 kg ha⁻¹ during *kharif* and *rabi* seasons of 2016-17 and 2017-18, respectively among different treatments. The highest K uptake was observed in 100% RDF +FYM + ZnSO₄ with 3.29, 4.15, 3.41, 4.21 kg ha⁻¹ which was significantly superior over remaining all the treatments in all four seasons of study and the lowest in control which was statistically inferior from all the treatments under study. The lowest value of iron uptake was in control and imbalanced fertilizer treatments whereas combined treatments and balanced dose of fertilizer treatments showed the highest value of iron uptake.

Among the inorganic treatments (T₂, T₃, T₄, T₅, T₆ and T₈), the highest iron uptake was observed in treatment T₆ and it was significantly superior over other treatments but however it was on par with treatment T₂. The treatments T₃, T₅ were on par with each other and significantly superior over T₄ and T₈. Similar results were obtained in all the crop growth stages during both the years of study in *kharif* and *rabi*.

There was a significant increase in the Fe concentration and uptake under continuous flooding due to the reduction of higher oxides and hydroxides of Fe into soluble form and thus increased availability of iron. Increase in uptake was due to higher availability of the plant nutrients from the soil reservoir and additional quantity of nutrients supplied by farm yard manure (Sharma and Dixit, 1987). N application might have enhanced the uptake of iron by changing rhizosphere pH. Similar results were reported by Singh *et al.* (1995) and Behara (2004).

Manganese uptake

Data on Mn uptake by rice at different growth stages in various treatments are presented in table (5 &6) Showed that significant variations on Mn uptake during both the years of study.

The highest manganese uptake at tillering stage, was observed in T₇ (100% RDF+ZnSO₄+FYM @ 5 t ha⁻¹) it was significantly superior over other treatments in *kharif* season. Whereas in *rabi*, the treatment T₇ was significantly superior over remaining treatments but however it was on par with T₆. Lowest (0.178, 0.251, 0.188, 0.259 kg ha⁻¹ in *kharif, rabi* 2016-17 and *kharif, rabi* 2017-18) manganese uptake was observed in untreated control (T₁).

Manganese uptake was ranged from 0.450 to 1.389 in *kharif*,16; 0.508 to 1.713 in *rabi*,17; 0.413 to 1.338 in *kharif*,17; 0.512 to 1.595 kg ha⁻¹ in *rabi*,18 at panicle initiation stage. The highest manganese uptake by rice was recorded by the treatment T₇ and it was significantly superior over other treatments but however it was on par with T₆ (100 % RDF + ZnSO₄) in *kharif* and *rabi* during both the years of study and lowest manganese uptake was observed in untreated control (T₁).

Comment [AB6]: Delete the word "was"

The highest Mn uptake by rice grain (0.305, 0.439, 0.291, 0.478 kg ha⁻¹) and straw (1.256, 1.593, 1.239, 1.645 kg ha⁻¹) was recorded in the treatment T₇ and it was significantly superior over other treatments but however it was on par with treatment T₆ in *kharif, rabi* during both the years of study. Lowest (0.089, 0.103, 0.063, 0.112 kg ha⁻¹ and 0.382, 0.537, 0.379, 0.552 kg ha⁻¹) in grain and straw, in *kharif, rabi* 2016-17 and 2017-18, respectively) manganese uptake was observed in untreated control (T₁).

The results revealed that the combined treatments increased manganese uptake it might be due to supply of this nutrient through organic manures further these organics might have increased the manganese availability through enhanced mineralization and chelation action which facilitated greater absorption and utilization of manganese. The earlier reports of Latha *et al.* (2002) supported the present findings.

Zinc uptake

Data pertaining to effect of organics, inorganics and their combination on Zn uptake by rice at different stages presented in table 1 and 2 revealed that there was a significant variation among treatments during both the years of study. It was obvious from the data the highest Zn uptake of rice was observed in the treatment T₇(100% RDF+ZnSO₄+FYM @ 5 t ha⁻¹) at tillering, panicle initiation, grain and straw at harvesting stage of rice during both the years of study in *kharif* and *rabi*.

At tillering stage the maximum zinc uptake (144.14, 265.41, 190.39, 278.16 kg ha⁻¹ respectively in *kharif*, *rabi* 2016-17 and *kharif*, *rabi* 2017-18, respectively) was recorded in the treatment T₇ (RDF +ZnSO₄ + FYM+ @ 5 t ha⁻¹), it was significantly superior over all other treatments in *kharif* season, whereas in *rabi*, the treatment T₇ was on par with T₆ and significantly superior over other treatments. As far as combined treatments (T₇, T₉, T₁₀ and T₁₁), the treatment T₇ was significantly superior over T₉, T₁₀ and T₁₁. The lowest zinc uptake (34.56, 54.49, 39.42, 54.75 kg ha⁻¹, respectively in *kharif*, *rabi* 2016-17 and *kharif*, *rabi* 2017-18) was recorded in the treatment T₁ (control).

Among the inorganic treatments of NPK (T₂, T₃, T₄, T₅ and T₈), the treatment T₂ was superior over treatments (T₃, T₄, T₅ and T₈). The enhancement of Zn content and its uptake due to FYM reported by Datta and Singh (2010).

The soil application of zinc sulphate significantly increased the zinc uptake by plants (Prasad and Umar, 1993). Higher Zn uptake under combined application N and ZnSO₄ was due to synergistic effect between N and Zn as reported by (Shanmugam and Veeraputhran, 2001).

Zinc uptake was ranged from 84.29 to 336.11 in *kharif*, 16; 113.92 to 420.83 in *rabi*, 17; 92.56 to 349.69 in *kharif*, 17; 109.61 to 385.83 kg ha⁻¹ in *rabi*, 18) at panicle initiation stage. The highest zinc uptake by rice was recorded by the treatment T₇ which was on par with T₆ (100 % RDF + ZnSO₄) and significantly superior over remaining treatments during first year study. In second year *rabi*, 2017 the treatment T₇ was significantly superior over remaining all other treatments. Lowest zinc uptake was observed in control (T₁), which was significantly lower compared to all other treatments. Dahdouhet *al.* (1999) found that organic manures played an

important role in nutrients solubility and activated physiological and biochemical processes in plant which led to increase of the plant growth and nutrient uptake.

Among the combined treatments (T₇, T₉, T₁₀ and T₁₁), the treatment which received 100% RDF+ ZnSO₄ + FYM @ 10 t ha⁻¹ (T₇) had maximum zinc uptake in rice grain with 180.19, 263.79, 199.32, 283.89 kg ha⁻¹, respectively in *kharif*, *rabi* during both the years of study and it was significantly superior over T₉, T₁₀ and T₁₁ and the lowest (46.08, 62.51, 44.95, 61.62 kg ha⁻¹, respectively in two years of study) zinc uptake was observed in control (T₁). Among the inorganic treatments of NPK (T₂, T₃, T₄, T₅ and T₈), the zinc uptake with 100% RDF (T₂) was highest which was significantly superior to T₃ (100% NK), T₄ (100 % PK), T₅ (100 % NP) and T₈ (50 % NPK). However, the treatments T₄, T₅ and T₈ were on par with each other.

Application of organics proved to increase the Zn uptake significantly by rice straw and grain as against the application of RDF alone (M₁). Application of organics increased the Zn uptake which might be due to greater availability of micronutrients in the soil as well as the organics. In majority of studies, there was a significant positive relationship between organic matter and available Zn in soils as also reported by (De *et al.*, 1994).

The zinc uptake by straw was ranged from 64.99 to 282.58; 118.89 to 392.45; 77.53 to 301.89; 125.92 to 413.79 kg ha⁻¹ during four seasons of study among different treatments. The highest zinc uptake was observed in 100% RDF + FYM + ZnSO₄ (T₇) followed by 100% NPK + ZnSO₄ (T₆) and 50% NPK + 50 % N through FYM (T₁₀) in *kharif* season. Whereas in *rabi* the treatment T₇ followed by T₆ and T₂. The lowest in control (T₁) which was significantly different from all the treatments under study. Among the combined treatments (T₇, T₉, T₁₀ and T₁₁), the treatment (T₇) had maximum zinc uptake in rice straw which was significantly superior over T₉, T₁₀ and T₁₁. However, the treatments T₉, T₁₀ and T₁₁ were on par with each other.

Higher uptake of nutrients in the treatments involving addition of FYM or GM along with fertilizers might be attributed to the extra amount of nutrients supplied by the FYM and GM, which influenced to increase the yield and ultimately showed higher uptake of nutrients. This was in agreement with the findings of Kumar and Yadav (1993).

Copper uptake

Results of the present investigation shown in reported that the copper uptake was significantly influenced by different treatments.

The highest cu uptake by rice at tillering stage was recorded in the treatment T₇ (45.72, 85.61, 50.26, 88.40 g ha⁻¹ in *kharif, rabi* 2016-17 and *kharif, rabi* 2017-18, respectively), which was on par with T₆ and significantly superior over remaining treatments in 2016-17. During the second year study (2017-18) the treatment T₇ was significantly superior over other treatments. Among the combined application of organic and inorganic fertilizer treatments (T₇, T₉, T₁₀, T₁₁), the significantly higher copper uptake was observed with the application of recommended dose of fertilizer (100% RDF) along with ZnSO₄ + FYM @ 5 t ha⁻¹ (T₇) which was significantly superior over T₉, T₁₀ and T₁₁. Among the T₉, T₁₀ and T₁₁ treatments, the treatment T₉ (50 % NPK + 50 % N through green manures) and T₁₀ (50 % NPK + 50 % N through FYM) were on par with each other and significantly superior over T₁₁ in all the seasons except in *Rabi*, 2018. These results were in line with the findings of Tyagi and Bhardwaj (1994) who revealed that FYM treated plots recorded the highest uptake of all the nutrients, indicating that the addition of FYM along with 100% NPK increased the uptake of nutrients to a greater extent in rice-wheat rotation. Lowest cu uptake (9.53, 13.21, 8.85, 13.65 g ha⁻¹ in *kharif, rabi* 2016-17 and *kharif, rabi* 2017-18 respectively) was observed in control (T₁).

At panicle initiation stage, among the inorganic treatments of NPK (T₂, T₃, T₄, T₅ and T₈), T₂ was superior over remaining treatments. However the treatments T₄, T₅ and T₈ were on par with each other. The treatments T₆ and T₂ were on par with each other in all the seasons except in *Kharif*, 17. Lowest copper uptake (22.58, 26.59, 18.23, 33.90 g ha⁻¹, in *kharif, rabi* 2016-17 and *kharif, rabi* 2017-18 respectively) was observed in control (T₁). The application of 100% NP and 100%NK treatment recorded decrease in copper uptake, whereas, the decreased was large under control. The highest copper uptake was observed in treatment T₇ (100% RDF+ ZnSO₄+ FYM) which was significantly superior over all other treatments in all the seasons except in *kharif* 17. Treatment T₇ was on par with T₆ and significantly superior over rest of the treatments in *kharif* 17.

These results were in conformity with the findings of Ghosh *et al.* (2001) who reported that application of FYM along with recommended dose of NPK fertilizer considerably increased the uptake of Cu by rice over RDF treatment.

The highest copper uptake by rice grain (29.31, 39.82, 27.95, 41.89 g ha⁻¹ in *kharif, rabi* 2016-17 and *kharif, rabi* 2017-18 respectively) was recorded in the treatment T₇ which was on par with the treatment T₆ with produced (27.41, 34.36, 26.43, 39.39 g ha⁻¹ in *kharif, rabi* 2016-17 and *kharif, rabi* 2017-18 respectively) and significantly superior over remaining treatments during both the years of study in all the four seasons. These results were in close conformity with the findings of Sriramachandrasekharan (2001) who reported the highest copper uptake with FYM application along with RDF. Lowest (10.91, 13.55, 9.25, 14.09 g ha⁻¹, in *kharif, rabi* 2016-17 and *kharif, rabi* 2017-18 respectively) in grain copper uptake was observed in untreated control (T₁).

The copper uptake by straw was ranged from 16.75 to 57.72; 26.54 to 91.86; 16.27 to 55.38; 26.78 to 97.31 g ha⁻¹ during *kharif, rabi* 2016-17 and *kharif, rabi* 2017-18. The highest copper uptake was observed in 100% RDF + FYM + ZnSO₄ (T₇) followed by 100% NPK + 50% NPK + 50% N through FYM (T₁₀) and 100% RDF + ZnSO₄ (T₆) in first year study. Whereas in the treatment T₇ followed by T₆ and T₁₀ in *kharif, 17*. In *rabi, 2018* the treatment T₇ followed by T₉ and T₁₀. The lowest in control (T₁) which was significantly different from all the treatments. Among the combined treatments (T₇, T₉, T₁₀ and T₁₁), the treatment which received 100% RDF + ZnSO₄ + FYM @ 5t/ha (T₇) had maximum copper uptake in rice straw which was on par with T₁₀ (50% NPK + 50% N through FYM) significantly superior over T₉ and T₁₁ in *kharif* season. Whereas in *rabi* the treatment T₇ was significantly superior over T₉, T₁₀ and T₁₁. This increase Cu uptake by grain and straw of rice might be due to increased Cu content.

Among the inorganic treatments (T₂, T₃, T₄, T₅, T₆ and T₈), the copper uptake with 100% RDF + ZnSO₄ (T₆) was highest and it was significantly superior over T₃, T₄, T₅ and T₈ but however it was on par with T₂. Similar results were observed in both the years of study in *kharif* and *rabi* in all the growth stages.

Das and Mandal (1986) reported that the uptake of Cu by the rice, straw and grain was found to be more in the rice plants grown under waterlogged condition. The higher Cu

uptake by the different plant parts of rice underwaterlogged condition could be explained due to favourable chemical environment of the rootmedium leading to higher root proliferation and nutrient absorption by the rice under reducing conditions.

Uptake of micronutrients was improved when organic manure was added along with chemical fertilizers. The increase in the uptake of cationic micronutrients with the application of FYM along with inorganic nitrogen might be due to the release of micronutrients on mineralization or production of organic acids during their decomposition which aids in solubilization of insoluble micronutrient compounds in soil or due to supply of natural chelating agents which render it more available.

CONCLUSIONS:

Data regarding all micro nutrient uptake by rice crop was higher with the application of 100% RDF in combination with ZnSO₄ and FYM @ 5t ha⁻¹ and it was significantly superior over other treatments but however it was on par with that of application of 100 % RDF along with ZnSO₄ @ 40 kg ha⁻¹ during both the years of the study in *kharif* and *rabi*. The application of 50 % NPK + 50 % N through FYM was on par with 100 % RDF. Uptake of all the macronutrients was markedly influenced by the treatments and the application of 100% RDF in combination with ZnSO₄ and FYM @ 5t ha⁻¹ recorded superior values than other treatments.
