Original Research Article

Studies on nutrient and weed dynamics on growth and yield attributes of direct seeded rice

ABSTRACT

Field experiment was carried out during *kharif* 2020 and 2021 at wetland farm of S. V. agricultural College, Tirupati, Andhra Pradesh. The experiment was laid out in a split plot design with three replications. The treatments consisted of three main plots *viz*., 100 % RDF (N_1), 125 % RDF (N_2) and 150 % RDF (N_3) and five sub plots *viz*., Pre emergence (PE) application of pyrazosulfuron-ethyl 25 g ha^{-1} *fb* penoxsulam + cyhalofop-p-butyl 125 g ha^{-1} at 20 DAS (W_1), Pre emergence (PE) application of pyrazosulfuron-ethyl 25 g ha^{-1} *fb* florpyrauxifenbenzyl + cyhalofop-p-butyl 150 g ha^{-1} at 20 DAS (W_2), Pre emergence (PE) application of pyrazosulfuron-ethyl 25 g ha^{-1} *fb* bispyribac-sodium 20 g ha^{-1} at 20 DAS (W_3), hand weeding twice at 20 and 40 DAS (W_4) and unweeded check (W_5). Nutrient levels and weed management practices significantly influenced the growth parameters *viz*., plant height, number of tillers m^{-2} and dry matter production and yield attributes *viz*., number of panicles m^{-2}, total number of grains $panicle^{-1}$ and number of filled grains $panicle^{-1}$ of direct seeded rice during both the years of investigation as well as in pooled mean. Interaction effect due to nutrient levels and weed management practices on growth parameters and yield attributes was found to be significant during both the years of study and in the pooled mean.

Keywords: Direct seeded rice, growth parameters, yield attributes

---

1. INTRODUCTION

Rice has been traditionally cultivated by transplanting seedlings into puddled soils and submerging the area. Standing water in the field causes macropore clogging, soil aggregate breakup in puddled soils, and the creation of hard pans beneath the subsurface layers of soils, as well as effective weed control. But, the sustainability of transplanted rice system is under

jeopardy due to several production-related constraints, *viz*., water, labour and energy scarcity, during peak period of demand and growing environmental concerns.

Transplanting of rice can be delayed due to late start of monsoon rainfall and the discharge of water into canals, as well as drudgery of puddling and physical transplanting. Under traditional system of rice cultivation, it takes around 5000 litres of water in order to produce 1 kg of rice (IRRI, 2001). A Review Pyrolysis: Different Agricultural Residues and Their Bio Char Characteristics (Makavana et al., 2021). As a result, rice production techniques that are not only able to cope with existing limits but also inexpensive, economically feasible, and capable of fulfilling future food demand must be investigated. In this context, direct seeded rice (DSR) is being assessed as viable alternative resource conservation method to address the problems interrelated with traditional rice farming in the face of looming agricultural resource shortages (Pandey and Velasco, 2002).

Direct seeded rice is subjected to greater weed competition than transplanted rice because both weed and crop seeds emerge at the same time and compete with each other right from its germination time resulting huge loss in grain yield (Rao *et al*., 2007). Diverse and intensified weed flora can be controlled by pre emergence herbicides in combination with post emergence herbicides. In addition to weed management problems in DSR, the nutrient management is also very difficult. Various researches under direct seeded rice have been conducted on nutrient and weed management practices in alone. The combined effect of nutrient levels and weed management practices may have different impacts than their individual effects considering better plant growth under effective weed management practices thus the nutritional requirement of the crop may change.

2. MATERIAL AND METHODS

The experiment was conducted during *kharif*, 2020 & 2021 at wetland farm of S. V. Agricultural College, Tirupati, Andhra Pradesh geographically situated at 13.5°N latitude and 79.5°E longitude and at an altitude of 182.9 m above the mean sea level in the Southern Agro-Climatic Zone of Andhra Pradesh. The experimental soil was sandy clay loam in texture, slightly alkaline in reaction, low in organic carbon and available nitrogen and medium in available phosphorus and available potassium. The treatments in main plot consisted of three nutrient

levels *viz*., 100 % RDF (N_1), 125 % RDF (N_2) and 150 % RDF (N_3) under main plots and five weed management practices comprised to sub plots *viz*., ., Pre emergence (PE) application of pyrazosulfuron-ethyl 25 g ha^{-1} *fb* penoxsulam + cyhalofop-p-butyl 125 g ha^{-1} at 20 DAS (W_1), Pre emergence (PE) application of pyrazosulfuron-ethyl 25 g ha^{-1} *fb* florpyrauxifenbenzyl + cyhalofop-p-butyl 150 g ha^{-1} at 20 DAS (W_2), Pre emergence (PE) application of pyrazosulfuron-ethyl 25 g ha^{-1} *fb* bispyribac-sodium 20 g ha^{-1} at 20 DAS (W_3), hand weeding twice at 20 and 40 DAS (W_4) and unweeded check (W_5). Pre emergence herbicide was applied immediately after sowing of rice crop and post emergence herbicides were imposed at 20 DAS. The rice variety chosen for the experiment was NLR-34449 and adopted a spacing of 20 cm x 10 cm. Nutrients *viz*., nitrogen, phosphorus and potassium in the form of urea, single super phosphate and muriate of potash, respectively were applied as per the treatments . Nitrogen was applied in three splits at 15 DAS, tillering and at panicle initiation stages. Entire quantity of phosphorus was applied at the time of sowing and potassium was applied in two splits, ½ at the time of sowing and the remaining ½ at panicle initiation stage. Observations on growth and yield attributes of direct seeded rice was recorded at the time of harvest and the data was statistically analyzed by following the analysis of variance for split plot design as suggested by the Panse and Sukhatme (1985). Statistical significance was tested with F test at 5 per cent level of probability and compared the treatmental means with critical difference.

3. RESULTS AND DISCUSSION

A. Effect of nutrient levels on growth and yield attributes of direct seeded rice

Growth parameters like plant height, number of tillers m^{-2} and dry matter production and yield attributes *viz*., number of panicles m^{-2}, total number of grains $panicle^{-1}$ and number of filled grains $panicle^{-1}$ at harvest followed similar trend. Significantly higher values of above parameters viz., plant height, number of tillers m^{-2}, dry matter production number of panicles m^{-2}, total number of grains $panicle^{-1}$ and number of filled grains $panicle^{-1}$ were obtained with 150 % RDF (N_3) than rest of the nutrient levels during both the years of study and in the pooled mean. Adequate supply of nutrients at different growth stages of crop might have enhanced the greater uptake of nutrients by the crop that lead to better crop growth. Similar results were reported by Kumar *et al*. (2022). The next best nutrient level in obtaining higher values was 125 % RDF (N_2)

which was significantly superior to 100 % RDF (N_1) during both the years of study and in the pooled mean.

B. Effect of weed management practices on growth and yield attributes of direct seeded rice

Among the different weed management practices, higher values of plant height, number of tillers m^{-2} and dry matter production and yield attributes *viz*., number of panicles m^{-2}, total number of grains $panicle^{-1}$ and number of filled grains $panicle^{-1}$ at harvest were obtained with hand weeding twice at 20 and 40 DAS (W_4) which was statistically comparable with PE application of pyrazosulfuron-ethyl 25 g ha^{-1} *fb* florpyrauxifenbenzyl + cyhalofop-p-butyl 150 g ha^{-1} at 20 DAS (W_2) during both the years of study and in the pooled mean. This might be due to reduced weed infestation as evident from lower weed density and biomass that facilitated for better utilization of growth resources which enhanced the vegetative and reproductive potential of the crop. The results are in accordance with those of Yadav *et al*. (2018). Advantage of Agrivoltaics across the Food-Energy-Water Connection makavana *et al.* (2020). The next best weed management practice was PE application of pyrazosulfuron-ethyl 25 g ha^{-1} *fb* penoxsulam + cyhalofop-p-butyl 125 g ha^{-1} at 20 DAS (W_1) followed by PE application of pyrazosulfuron-ethyl 25 g ha^{-1} *fb* bispyribac-sodium 20 g ha^{-1} at 20 DAS (W_3) with significant disparity among them. The lowest values of plant height, number of tillers m^{-2} and dry matter production and yield attributes *viz*., number of panicles m^{-2}, total number of grains $panicle^{-1}$ and number of filled grains $panicle^{-1}$ at harvest were registered with unweeded check (W_5) during both the years of study and in the pooled mean. This was obviously due to severe competition offered by the weeds for growth resources right from the seedling emergence leading to poor crop growth and inefficient translocation of photosynthates from source to sink which lead to diminished yield attributes of rice.

Among the various combinations of nutrient levels and weed management practices, significantly higher plant height, number of tillers m^{-2} and dry matter production and yield attributes *viz*., number of panicles m^{-2}, total number of grains $panicle^{-1}$ and number of filled. Development of Solar Operated Walking Type Power Weeder kachhot *et al.* (2020).

W at N	**3.4**	**10**	**3.3**	**10**	**3.4**	**10**

grains panicle^{-1} at harvest were observed with 150 % RDF coupled with hand weeding twice at 20 and 40 DAS (N_3W_4) which was statistically comparable with 125 % RDF coupled with hand weeding twice at 20 and 40 DAS (N_2W_4) and 150 % RDF coupled with PE application of pyrazosulfuron-ethyl 25 g ha^{-1} *fb* florpyrauxifenbenzyl + cyhalofop-p-butyl 150 g ha^{-1} at 20 DAS (N_3W_2). The lowest value of plant height, number of tillers m^{-2} and dry matter production and yield attributes *viz*., number of panicles m^{-2}, total number of grains panicle^{-1} and number of filled grains panicle^{-1} at harvest were noticed with 100 % RDF in combination with unweeded check (N_1W_5) during both the years of study and in the pooled mean.

4. CONCLUSION

From the present investigation it was concluded that among nutrient levels, 150 % RDF was found to be significant superior to other nutrient levels. Among various weed management practices, hand weeding twice at 20 and 40 DAS (W_4) which was statistically comparable with PE application of pyrazosulfuron-ethyl 25 g ha^{-1} *fb* florpyrauxifenbenzyl + cyhalofop-p-butyl 150 g ha^{-1} at 20 DAS (W_2).
