

Menetrier Disease: A Nephrotic Syndrome of the Stomach

ABSTRACT

Menetrier Disease (MD) is a rare acquired disease that affects middle-aged men in their mid 40's and, to a lesser extent, women and children. Pierre Eugene Menetrier first described it. It is a premalignant disorder, sometimes associated with *Helicobacter Pylori* in adults and Cytomegalovirus in children. The enlargement of the rugae folds in the stomach results from excess mucous production due to hyperplasia of the foveolar glands from excessive secretion of transforming growth factor alpha (TGF- α). Atrophy of other glands resulting in anemia, hypoproteinemia, and edema are distinguishing characteristics of the pathology. Diagnosis is made by barium esophagogram, esophagogastroduodenoscopy (EGD), and serology. A monoclonal antibody called cetuximab (anti-EGFR) is the first treatment for Menetrier disease. Other supportive therapies are regimens for peptic ulcer disease, proton pump inhibitors, anticholinergic drugs, steroids, a high-protein diet, and gastrectomy. Prognosis is better for children than adults because of high risk of developing gastric cancer. The review article aims to discuss this rare gastric mucosa (foveolar) disorder called Menetrier and support integration, research and learning among medical students and health professionals.

Keywords: Menetrier syndrome, hypertrophy of the stomach, H.pylori, EGFR, TGF.

INTRODUCTION

Menetrier disease, also known as the nephrotic syndrome of the stomach, protein-losing gastropathy, or hypoproteinemic hypertrophic gastropathy. It is a rare acquired disease noted for the cerebriform-like enlargement of the rugae folds seen in the fundus and body of the stomach.

Figure 1 – The stomach

Source: <https://www.biusante.parisdescartes.fr/histoire/medica/resultats/index.php?do=page&cote=epo0671&p=1>

In 1888 the French surgeon, oncologist, and pathologist Pierre Eugene Menetrier first described a rare gastric disorder after a post-mortem study on cadavers.[1]The name Menetrier disease is sometimes used to describe any condition with large (hypertrophied) gastric folds. While some researchers believe that Menetrier disease and giant hypertrophic gastritis may be variants of the same disorder spectrum, a diagnosis of Menetrier is based on the presence of large gastric folds due to the overgrowth of mucous cells. *There is little or no

stomach inflammation, and Menetrier disease is a form of hyperplastic gastropathy. [2]

It has been associated with Cytomegalovirus (CMV) infection in children and the gram-negative curvilinear bacteria known as Helicobacter Pylori (H. pylori) in adults. **The release of excessive Transforming Growth Factor- α (TGF- α) is caused by hyperplasia of the mucous forming foveolar glands. These excess proteins leak from the bloodstream into the stomach, resulting in hypoproteinemia.** The hyperplasia also leads to the atrophy of other glands, causing a decrease in the level of pepsinogen, hydrochloric acid, and Intrinsic factor. These morphological changes may result in anemia, generalized pitting edema, and gastric adenocarcinoma. [3] Diagnosis is usually by barium study, endoscopy with biopsy, and serology. Treatment recommendations are oral drugs for peptic ulcer disease, a high protein diet, chimeric monoclonal antibodies (Cetuximab), or, if necessary, gastrectomy. Prognosis is good for children, but it may lead to carcinoma or lymphoma in adults. [4]

Epidemiology

Menetrier Disease is a rare, **fatal** disease affecting both children and adults. There has been difficulty estimating the prevalence of the disease because of challenges in diagnosis. However, less than 1000 cases are reported with slightly more males than females, particularly those between the ages of 30 and 60 years. [5] A childhood form exists, and there have been reports of affected siblings suggesting a genetic involvement. There is also a variant linked with cytomegalovirus, accounting for 50-60 cases per year. The survival rate was 73% after five years and 65% after ten years. [6]

Etiology

The cause of Menetrier disease is not fully understood. It is believed to be an acquired disease rather than

inherited. [8] There have been a few rare cases of siblings developing the disease, thought to be an autosomal dominant mode of inheritance. Many adult cases have been associated with the Helicobacter Pylori infection and children with the CMV Virus. [7][9] H. pylori and CMV may not be the precursor agents of the disease process but a factor that contributes to the hyperplasia of the mucous forming foveolar glands, which increases the release of excessive Transforming Growth Factor- α (TGF- α). H. pylori and CMV are not always observed. [8]

PATHOPHYSIOLOGY

The Pathophysiology of Menetrier Disease is not fully understood, **but some mouse models that overexpressed TGF- α showed epithelial hyperplasia of various organs, including the stomach.** This overexpression of TGF- α produced characteristic presentations such as foveolar hyperplasia, glandular cystic dilatation, oxyntic atrophy, increased mucin production, and reduced acid secretion. [9] [15] [16]

Mouse studies have been conducted to explore the pathophysiology of Menetrier disease. These studies showed that hyperplasia of foveolar mucous cells is involved with upregulation in the epidermal growth factor receptor (EGFR) signaling. This subsequently leads to increased production of TGF- α by a factor of 1.5 to 2.1 times and in the growth of the gastric epithelial cells. [9][14] The overproduction of the mucosa presents as the large rugae folds. The proteinaceous mucous produced by these cells is increased, and the excess mucous is secreted into the lumen of the stomach and passed out with feces. [10] [14]

The excess TGF- α production and excess mucous production also lead to the atrophy of the chief and parietal cells. The chief cells are involved in the production of pepsinogen, so there is decreased pepsin with the atrophy of these cells. Pepsin is involved in the breakdown of proteins. The excretion of the excess

mucous and the undigested proteins leads to severe Hypoproteinaemia.[11] [14]

The Parietal cells are involved in producing hydrochloric acid (HCl) and Intrinsic Factor (IF). **The reduced HCl results in less availability of hydrogen ions (H+), activating G-cells to produce more gastrin???.sideropenia???**The intrinsic factor is a glycoprotein that binds vitamin B12 (cobalamin) and enables absorption at the terminal ileum. **Pernicious anemia (PA)**is megaloblastic anemia and may result from a cobalamin deficiency. [12] [15]

The protein-losing gastropathy can lead to hypoproteinemia, decreasing the oncotic plasma pressure and leading to pitting edema.[13]

CLINICAL PRESENTATIONS

Typically, a patient would present with abdominal pain, nausea,protein-losing malnutrition, vomiting, diarrhea, abdominal pain, weight loss, and peripheral edema due to protein and albumin loss. In some cases, megaloblastic anemia may occur, characterized by symptomatology of anemia, neurological manifestations, and mild jaundice[13][16]. There is often a gradual onset of symptoms progressively worsening. There have been reports of abrupt onset and spontaneous remission, often associated with acytomegalovirus (CMV) in children or a Helicobacter pylori infection in adults.[14] [15]

DIAGNOSIS

Menetrier disease can be accurately diagnosed using the following clinical histopathological procedures:

- 1) **Endoscopic exams and Biopsy:**are used to examine the interior of the stomach. The pronounced large gastric folds in the gastric body will be observed. [17]The folds are not seen in the antrum. A histopathological study of a tissue sample obtained during the procedure is used to support the Diagnosis.

Source: [Ménétrier's Disease: Its Mimickers and Pathogenesis - PMC \(nih.gov\)](#)

The histology of Menetrier disease reveals foveal hyperplasia with corkscrew morphology and cystic dilated deep glands. Linear architecture is maintained. A full-thickness mucosal biopsy will identify the deep glandular loss. There is a lack of inflammatory cells, intestinal metaplasia, or dysplasia. At times there is the presence of eosinophils, plasma cells, hyperplasia of smooth muscle, and edema. There is a loss of parietal cells due to atrophic oxyntic glands.

Source: [Ménétrier's Disease: Its Mimickers and Pathogenesis - PMC \(nih.gov\)](#)

- 2) **Barium Meal:** Barium is a naturally occurring element given as a drink that coats the walls of the digestive tract and appears white on the X-ray. The barium swallow reveals enlarged folds in the greater curvature of the stomach. [17][18]

Figure 6 - Barium swallow revealing enlarged folds along greater curvature in the stomach – Rev Assoc Med Bras 2017

Source: [Ménétrier's Disease: Its Mimickers and Pathogenesis - PMC \(nih.gov\)](#)

- 3) **Abdominal computed tomography(CTscan):** This reveals diffusely enlarged rugal folds that project into the lumen of the gastric fundus and body. The antrum is spared. [15]

Figure 7 - Axial contrast material-enhanced CT image at the level of the gastric fundus shows gastric wall thickening and enhancement (arrow)Source: Radiographics (2009).

Figure 8 - Axial contrast-enhanced CT image of the distal stomach reveals that the body is primarily involved, and the antrum is relatively spared (arrows)
Source: Radiographics (2009).

4) **Laboratory evaluations:** Include Polymerase chain reaction (PCR) confirming the presence of Cytomegalovirus (CMV) and H. Pylori. Other possible suggestive investigations are:[16][17]

- Compete blood count may showing Lymphopenia.
- Serum level of albumin reveals hypoalbuminemia and reduced globulin.
- Increased level of TGF- α
- Gastric pH which increases to 4-7 (normal 1-3)
- Alpha-1-antitrypsin elevation.
- Elevated serum gastrin level.

- Iron deficiency anemia and Hypochromic microcytic anemia.

A flow chart outlining the diagnosis decision-making steps for Menetrier Disease:

Associated Diseases

Menetrier Disease may be associated with other unrelated diseases, and that may cause variation in its clinical manifestations.

Cases with autoimmune diseases such as inflammatory bowel disease, sclerosing cholangitis, and ankylosing have been reported in Menetrier Disease.[18]

There is an increased risk of gastric cancer, and 8.9% of patients developed gastric cancer after 10 years of follow-up.[19]

DIFFERENTIALS

Diseases that present with thickened gastric folds must be differentiated from Menetrier. [1][21][22]The correlation of histological findings with clinical features is important in establishing an accurate diagnosis.

Zollinger-Ellison syndrome - peptic ulcers in the GI tract and parietal cell hyperplasia. [22]

H. pylori gastritis - Gastritis is present with a positive *H. pylori* test. Gastritis is not found in Menetrier Disease. [22]

Hypertrophic lymphocytic gastritis - presents with severe inflammation with predominant intraepithelial lymphocytes. [22]

Gastric polyps- more focal and can be numerous, mimicking Menetrier disease. [22]

Gastric adenocarcinoma - dysplasia and loss of structure differentiate this from Menetrier syndrome. [22]

Other infectious conditions like histoplasmosis, syphilis, tuberculosis and infiltrative disorders such as sarcoidosis can also present similar to Menetrier

disease. [20] [22] It is, therefore, imperative to rule out some of these conditions in some cases (Table 1). [22]

Diagnosis	Distribution	Location in stomach	Hyperplastic mucosal compartment	Pathologic features
Ménétrier's disease	Diffuse	Body and fundus; relative sparing of antrum	Foveolar epithelium	Massive foveolar hyperplasia
Hypertrophic lymphocytic gastritis	Diffuse	Body and fundus; relative sparing of antrum	Foveolar epithelium	Prominent intraepithelial lymphocytes
Hypertrophic hypersecretory gastropathy	Diffuse	Body and fundus; atrophic antrum	All layers	Hyperplasia of all glandular compartments
Zollinger-Ellison syndrome	Diffuse	Body and fundus	Parietal cells	Parietal cell hyperplasia
Hyperplastic polyp	Focal	Antrum; body and fundus also possible	Foveolar epithelium	Foveolar hyperplasia with architectural distortion
Polyposis syndrome with hamartomatous polyps	Variable	Body, fundus, and antrum	Foveolar epithelium	Features similar to hyperplastic p
Gastric adenocarcinoma and proximal polyposis of the stomach	Variable	Body and fundus	Oxyntic glands	Fundic gland polyps with low and high-grade dysplasia
Diffuse gastric carcinoma	Variable	Body, fundus, and antrum	Not applicable	Infiltrating carcinoma; diffuse typ
Lymphoma	Variable	Body, fundus, and antrum	Not applicable	Effacement of gastric mucosa by infiltrating lymphoma cells
Amyloidosis	Variable	Body, fundus, and antrum	Not applicable	Acellular, amorphous eosinophilic material surrounding glands and

MANAGEMENT

Treatment of Menetrier disease may be spontaneous or remission with the use of medications, intravenous protein and albumin, blood transfusions, and surgery. [21][24] [26] [29]

Cases that have tested positive for H. Pylori or CMV infections are treated with respective antibiotics, proton-pump inhibitors and antiviral medications first. [22][25][28]

A high protein diet is recommended. If necessary, intravenous protein, albumin, and blood transfusions are used for malnourished or anemic cases. [23] In most cases, children who have had a CMV infection fully

recovered after treatment for the virus, along with appropriate protein and anemia treatment. [25]

An anti-cancer drug Cetuximab (Erbix), given intravenously, has been shown to reduce the thickness of the stomach wall from the overgrowth of mucous cells by blocking the activity of epidermal growth factor (TGF- α) and significantly improving symptoms. [27][30] Patients must be monitored carefully for side effects. This is the first-line treatment for MD. [5][22]

Oral medications like proton pump inhibitors for peptic ulcer disease and metoclopramide for controlling nausea, vomiting, and abdominal pain may also be prescribed. [28][29]

Gastrectomy may be required to remove a part or all of the stomach in severe cases or index of suspicion of malignant transformation. [26]

CONCLUSION

Menetrier disease is associated with excessive TNF alpha in the gastrointestinal tract, causing foveolar surface mucus cell hyperplasia and increased epidermal growth factor receptor (EGFR) signaling. [27] This disease is also known as the nephrotic syndrome of the stomach, protein-losing gastropathy, or hypoproteinemic hypertrophic gastropathy. [23] It may be due to exposure to CMV in children or H. Pylori in adults. It is seen slightly more in middle-aged men than women. [25]

Menetrier Disease's hallmark is the cerebrum enlargement of rugal folds in the stomach, mainly affecting the fundus and body. [7] This hyperplasia causes atrophy of the chief and parietal cells, affecting protein metabolism and leading to protein-losing gastroenteropathy. Another complication of Menetrier disease is anemia. Hyperplasia is also associated with an increase in the risk of adenocarcinoma. [7] [26] Diagnosis of the disease has been made using x-ray barium studies, biopsy, and serology. [1][17][18] Treatment aims to eliminate H. pylori, treat with ganciclovir, cetuximab, a high protein diet, or oral drugs used for Peptic ulcer disease. [25][27][30] Gastrectomy is used if the former

treatments are not effective.[26][30]The prognosis for children is good as the disease is self-limiting, while it may lead to primary gastric carcinoma or lymphoma in adults.
