

# Energy Balance Studies of Weed Management Practices in Mustard (*Brassica juncea* (L.) Czernj and Cosson)

## ABSTRACT

A field experiment was conducted at College Farm, College of Agriculture, Rajendranagar, Hyderabad during *rabi* 2020-21 on loamy sand soils to study energy balance of weed management practices in mustard. The energy balance studies were determined by using direct and indirect energy. Among the different weed management practices, pendimethalin 30 % EC 1.0 kg ha<sup>-1</sup> PE *fb* straw mulch 5 t ha<sup>-1</sup> recorded higher energy input. This treatment was followed by oxyfluorfen 23.5 % EC 0.1 kg ha<sup>-1</sup> PE *fb* straw mulch 5 t ha<sup>-1</sup> and oxadiargyl 6 % EC 0.09 kg ha<sup>-1</sup> PE *fb* straw mulch 5 t ha<sup>-1</sup>. Maximum energy output, net energy, energy use efficiency and energy productivity were noticed under intercultivation and hand weeding at 15 and 30 DAS and it was statistically on par with oxadiargyl 6 % EC 0.09 kg ha<sup>-1</sup> PE *fb* intercultivation at 30 DAS, oxyfluorfen 23.5 % EC 0.1 kg ha<sup>-1</sup> PE *fb* intercultivation at 30 DAS and pendimethalin 30 % EC 1.0 kg ha<sup>-1</sup> PE *fb* intercultivation at 30 DAS.

**Key words:** Energy input, Energy output, Energy efficiency, Energy Productivity and Intercultivation,

## INTRODUCTION:

Mustard is one of the most important oilseed crops in terms of worldwide trade. It is a member of the Cruciferae family. It is the second most important oilseed crop in India, after groundnut, among the seven edible oilseeds. Mustard seeds have an oil content ranging from 37 to 49% (Bhowmik *et al.*, 2014). In India, rape seed and mustard occupy 6.23 million ha area with production and productivity of 9.34 million tonnes and 1499 kgha<sup>-1</sup> respectively (India stat 2019-20). Weeds are the major biotic stress in mustard production. With the intensification of agriculture, the use of non-farm inputs such as fertilizers, insecticides, herbicides, fungicides and various other chemicals has been increased with the time. The requirement of the energy for these inputs is high. With the increasing

crude oil prices day by day which in turn increases the price of the external inputs. Thus the cost of cultivation multiplies with the benefits being limited. Hence the calculation of energy inputs and outputs is inevitable. Energy balance is defined as the measurement of proportion as well as analysis of the energy input consumed and output produced out of different activities to find out the direction of energy consumption pattern of a system (Acharya *et al.*, 2013). Keeping this in view, the present experiment was carried out with the objective to study energy balance of weed management practices in mustard. The energy balance studies were carried out for the practices adopted from the start of crop cultivation to the end of harvest.

## MATERIAL AND METHODS

A field experiment was conducted during *rabi* season 2020-21 at College Farm, College of Agriculture, Rajendranagar, Hyderabad. The experimental field's soil had a loamy sand texture and a pH of 7.9 with available nitrogen ( $223 \text{ kg ha}^{-1}$ ), available phosphorus ( $30.87 \text{ kg ha}^{-1}$ ), available potassium ( $375.72 \text{ kg ha}^{-1}$ ) and organic carbon (0.69%), it was medium fertile. Mustard variety NRCHB-101 was sown with seed rate of  $4 \text{ kg ha}^{-1}$ . The seeds were sown manually with spacing of  $40 \times 10 \text{ cm}$ . Recommended dose of fertilizers 80:40:40  $\text{Kg ha}^{-1}$  N,  $\text{P}_2\text{O}_5$   $\text{K}_2\text{O}$  were applied. The experiment was laid out in randomised block design replicated thrice with twelve treatments *viz.*, T<sub>1</sub>: Pendimethalin 30 % EC  $1.0 \text{ kg ha}^{-1}$  PE *fb* quizalofop ethyl 5% EC  $0.05 \text{ kg ha}^{-1}$  PoE, T<sub>2</sub>: Oxadiargyl 6% EC  $0.09 \text{ kg ha}^{-1}$  PE *fb* quizalofop ethyl 5% EC  $0.05 \text{ kg ha}^{-1}$  PoE, T<sub>3</sub>: Oxyfluorfen 23.5 % EC  $0.1 \text{ kg ha}^{-1}$  PE *fb* quizalofop ethyl 5% EC  $0.05 \text{ kg ha}^{-1}$  PoE, T<sub>4</sub>: Pendimethalin 30 % EC  $1.0 \text{ kg ha}^{-1}$  PE *fb* straw mulch  $5 \text{ t ha}^{-1}$ , T<sub>5</sub>: Oxadiargyl 6% EC  $0.09 \text{ kg ha}^{-1}$  PE *fb* straw mulch  $5 \text{ t ha}^{-1}$ , T<sub>6</sub>: Oxyfluorfen 23.5 % EC  $0.1 \text{ kg ha}^{-1}$  PE *fb* straw mulch  $5 \text{ t ha}^{-1}$ , T<sub>7</sub>: Pendimethalin 30 % EC  $1.0 \text{ kg ha}^{-1}$  PE *fb* intercultivation at 30 DAS, T<sub>8</sub>: Oxadiargyl 6% EC  $0.09 \text{ kg ha}^{-1}$  PE *fb* intercultivation at 30 DAS, T<sub>9</sub> : Oxyfluorfen 23.5 % EC  $0.1 \text{ kg ha}^{-1}$  PE *fb* intercultivation at 30 DAS, T<sub>10</sub>: Intercultivation and hand weeding at 15 and 30 DAS (weed free), T<sub>11</sub>: Intercultivation at 15 and 30 DAS, T<sub>12</sub>: Unweeded control. Pre-emergence herbicides were applied within in 24 hours after sowing. All post-emergence herbicides were

sprayed at 2-3 leaf stage of weeds. Straw mulch was laid at 15 DAS. Intercultivation was done with push hoe at 15 and 30 DAS. Hand weeding was done at 15 and 30 DAS. The observations were noticed on energy input, energy output, net energy, energy efficiency, energy Productivity.

Energy input of different treatments was estimated by using direct and indirect energy. Direct energy inputs include total quantity of fossil fuel used in land preparation, harvesting, human labour and electricity whereas indirect energy inputs are energy used in transportation of machinery synthetic fertilizers, pesticides and seed. The indirect energy use of agricultural machinery was calculated by using an equation.

$$E_{im} = (MTR \times M) / (L \times C_e)$$

Where,  $E_{im}$  = Machinery input energy (M)  $ha^{-1}$ )

MTR = Energy used to manufacture, transport and repair

M = Mass of machinery (kg)

L = Life of machinery (h)

$C_e$  = Effective field capacity of farm machinery ( $h\ ha^{-1}$ ).

### **Output energy**

The seed and stover yields were considered for calculating output energy. Energy output was calculated by multiplying the seed and stover yields with corresponding energy coefficient. Energy efficiencies or intensities of the different weed management treatments were estimated as i) net energy and ii) ratio of output to energy input (Energy use efficiency, EUE).

### **Total net energy**

$$NE_t = \text{Energy Output} - \text{Energy input}$$

### **Total energy use efficiency**

$$\text{Total energy output (MJ } ha^{-1}\text{)}$$

$$\text{EUEt} = \frac{\text{Total yield (kg ha}^{-1}\text{)}}{\text{Energy input (MJ ha}^{-1}\text{)}}$$

**Total energy productivity**

$$\text{EPt} = \frac{\text{Total yield (kg ha}^{-1}\text{)}}{\text{Energy input (MJ ha}^{-1}\text{)}}$$

## RESULTS AND DISCUSSION

### Effect on weed flora

The experimental field was infested with grasses like *Digitaria sanguinalis*, *Chloris barbata*, *Echinochloa crusgalli*, *Cynodon dactylon*, *Dactyloctenium aegyptium*, *Dinebra retroflexa*, *Eleusine indica* and sedges like *Cyperus rotundus* and broad-leaved weeds like *Parthenium hysterophorus*, *Alternanthera sessilis*, *Trianthema portulacastrum*, *Cleome viscosa*, *Datura stramonium*, *Euphorbia hirta*, *Commelina benghalensis*, *Sonchus arevensis* and *Digera arvensis*.

### Effect on weed control efficiency

Different weed management practices had impact on weed control efficiency (Table 1). Higher weed control efficiency was

observed with intercultivation and hand weeding at 15 and 30 DAS and this treatment was followed by oxadiargyl 6 % EC 0.09 kg ha<sup>-1</sup> PE *fb* intercultivation at 30 DAS, oxyfluorfen 23.5 % EC 0.1 kg ha<sup>-1</sup> PE *fb* intercultivation at 30 DAS, pendimethalin 30 % EC 1.0 kg ha<sup>-1</sup> PE *fb* intercultivation at 30 DAS, oxadiargyl 6 % EC 0.09 kg ha<sup>-1</sup> PE *fb* straw mulch at 5 t ha<sup>-1</sup>, oxyfluorfen 23.5 % EC 0.1 kg ha<sup>-1</sup> PE *fb* straw mulch at 5 t ha<sup>-1</sup>, pendimethalin 30 % EC 1.0 kg ha<sup>-1</sup> PE *fb* straw mulch at 5 t ha<sup>-1</sup>, intercultivation at 15 and 30 DAS, It might be due to effective control of weeds led to reduced weed dry matter resulted in higher weed control efficiency (Singh and Kumar, 2020).

### **Effect on yield**

Data pertaining to yield presented in Table 1. Among weed management practices, Higher seed and stover yield were observed under intercultivation and hand weeding at 15 and 30 DAS and it was on par with oxadiargyl 6% EC 0.09 kg ha<sup>-1</sup> PE *fb* intercultivation at 30 DAS. In turn oxadiargyl 6% EC 0.09 kg ha<sup>-1</sup> PE *fb* intercultivation at 30 DAS on par with oxyfluorfen 23.5 % EC 0.1 kg ha<sup>-1</sup> PE *fb* intercultivation at 30 DAS, pendimethalin 30 % EC 1.0 kg ha<sup>-1</sup> PE *fb* intercultivation at 30 DAS. Effective control of weeds provided congenial environment for crop which resulted in higher yield attributes led to higher yield (Das, 2016).

### **Energy balance studies**

Data pertaining to energy balance studies were presented in Table 2. Among the different weed management practices, pendimethalin 30 % EC 1.0 kg ha<sup>-1</sup> PE *fb* straw mulch 5 t ha<sup>-1</sup> recorded highest energy input. This treatment was followed by oxyfluorfen 23.5 % EC 0.1 kg ha<sup>-1</sup> PE *fb* straw mulch 5 t ha<sup>-1</sup> and oxadiargyl 6 % EC 0.09 kg ha<sup>-1</sup> PE *fb* straw mulch 5 t ha<sup>-1</sup> it might be due to more energy necessary to produce straw mulch.

Higher total energy output was observed with intercultivation and hand weeding at 15 and 30 DAS and it was statistically on par with oxadiargyl 6 % EC 0.09 kg ha<sup>-1</sup> PE *fb* intercultivation at 30 DAS. Oxadiargyl 6 % EC 0.09 kg ha<sup>-1</sup> PE *fb* intercultivation at 30 DAS

in turn on par with oxyfluorfen 23.5 % EC 0.1 kg ha<sup>-1</sup> PE *fb* intercultivation at 30 DAS and pendimethalin 30 % EC 1.0 kg ha<sup>-1</sup> PE *fb* intercultivation at 30 DAS.

Intercultivation and hand weeding at 15 and 30 DAS was recorded significantly higher net energy and it was found to be on par with oxadiargyl 6 % EC 0.09 kg ha<sup>-1</sup> PE *fb* intercultivation at 30 DAS. Oxadiargyl 6 % EC 0.09 kg ha<sup>-1</sup> PE *fb* intercultivation at 30 DAS in turn on par with oxyfluorfen 23.5 % EC 0.1 kg ha<sup>-1</sup> PE *fb* intercultivation at 30 DAS, pendimethalin 30 % EC 1.0 kg ha<sup>-1</sup> PE *fb* intercultivation at 30 DAS.

Significantly superior energy use efficiency (EUE) of total output was recorded under intercultivation and hand weeding at 15 and 30 DAS and it was statistically on par with oxadiargyl 6 % EC 0.09 kg ha<sup>-1</sup> PE *fb* intercultivation at 30 DAS, oxyfluorfen 23.5 % EC 0.1 kg ha<sup>-1</sup> PE *fb* intercultivation at 30 DAS and pendimethalin 30 % EC 1.0 kg ha<sup>-1</sup> PE *fb* intercultivation at 30 DAS.

Intercultivation and hand weeding at 15 and 30 DAS was recorded highest energy productivity (EP) of total output and it was statistically on par with oxadiargyl 6 % EC 0.09 kg ha<sup>-1</sup> PE *fb* intercultivation at 30 DAS, oxyfluorfen 23.5 % EC 0.1 kg ha<sup>-1</sup> PE *fb* intercultivation at 30 DAS and pendimethalin 30 % EC 1.0 kg ha<sup>-1</sup> PE *fb* intercultivation at 30 DAS. Similar results were noticed by Jha *et al.* (2020).

## CONCLUSIONS

In case of energy balance studies, maximum energy input was required for pendimethalin 30 % EC 1.0 kg ha<sup>-1</sup> PE *fb* straw mulch 5 t ha<sup>-1</sup>. Higher energy output, net energy, energy use efficiency and energy productivity were recorded under Intercultivation and hand weeding at 15 and 30 DAS.
