

Enumeration of cyclic codes over $GF(23)$

Abstract

In this paper, we investigate the number of irreducible polynomials of $x^n - 1$ over $GF(23)$. First, We factorize $x^n - 1$ into irreducible polynomials over $GF(23)$ using the cyclotomic cosets of 23 modulo n . The number of irreducible polynomial factors of $x^n - 1$ over $GF(23)$ is equal to the number of cyclotomic cosets of 23 modulo n and each monic divisor of $x^n - 1$ is a generator polynomial of cyclic codes in $GF(23)$. Succeedingly, we confirm that the number of cyclic codes of length n over a finite field $GF(23)$ is equivalent to the number of polynomials that divide $x^n - 1$.

In conclusion, we enumerate the number of cyclic codes of length n for $1 \leq n < 24$ and as $n = 23k, n = 23^k$ for $1 \leq k < 24$

1 Introduction

Most investigations and explanations executed in coding theory are persuaded largely by the vexaticity of codes that subsist effectiveness and efficiency in certain functioning along with the deligence with regard to decoding complications of coding theory particularly in communication through deceptive carriers whose outcomes are inaccurate in the conveyed acceptation. It is significant perceiving that the theory of error-correcting concern on an account of the assumed recalcitrant of auditioning message accurately. Entropy is consigned along a channel that is liable to inaccuracy. The medium can be a telephone line, a high frequency radio network in turn with satellite delivery link. The noise can be humanoid errors, lightning, thermal noise deficiency in accessories e.t.c. The goal of

on error correcting intend to encode the finding affixing considerable redundancy to the message in that the foremost message can be recovered. Researchers consequently chase down for an (n, k, d) – code with disseminate an extensive collection of messages efficiently and correct multiple errors particularly small n , large k , and large d . These are contradicting aims and this is usually pertained to as the utmost coding theory problem. Along with these practicable applications, encoding theory has multiple applications in the theory of computer science. As such it is a concept of significance to both practitioners and theoreticians.

1.1 Definitions

i) **Code:** Let \mathbb{F} be a finite set with q elements, there are q^n different sequences of length n , of these only q^k are codewords since the r check digits within any codeword are completely determined by k message digits. The set consisting of q^k codewords of length n is called a code. The length n is a range of n -tuples $(a_1, a_2, a_3, \dots, a_n)$ where the a_i 's belong to a finite set \mathbb{F} beside two symbols or digits called alphabets hence, a code of length n from \mathbb{F} is on element of \mathbb{F}^n (the set of all n -tuples from \mathbb{F}).

ii) **Cyclic code:** A linear block is stated to be cyclic code when it is constant under entire cyclic shifts that is if $a_0, a_1, a_2, \dots, a_n$ is codeword, therefore $a_n, a_1, a_2, \dots, a_{n-1}$ and $a_2, a_3, \dots, a_n, a_1$, This indicate that a cyclic code is achieved by a cyclic right shift of the determinant is also a codeword and this furthermore implicate the left shift. Consequently a linear code C is cyclic absolutely so long as it is an invariant under all cyclic shifts.

iii) **Cyclotomic cosets:** Let n be co-prime to q , the cyclotomic cosets of $n \bmod q$ containing i is defined by:

$$C_i = \{i \cdot q^j \bmod n \in \mathbb{Z}_n : \{j = 0, 1, 2, 3, \dots\}$$

A subset $\{i_1, i_2, \dots, i_n\}$ of \mathbb{Z}_n is called a a complete set of representatives of cyclotomic cosete of $q \bmod n$ if $C_{i_1}, C_{i_2}, \dots, C_{i_n}$, is distinguishable and $U_j^i = 1, C_{j^2}^i = \mathbb{Z}_n$.

2 Main Results:

A code C is shown to be cyclic when and only when it is a linear code and its invariant under way every cyclic shift. In finding cyclic codes we factorize $x^n - 1$ into irreducible polynomials and achieve all monic polynomials that divide $x^n - 1$. Every such monic polynomial is a generator polynomial and generate a cyclic code. Afterwords we generate the number of cyclic codes of length n over GF(23)

2.1 Factorization of $x^n - 1$ into irreducible polynomial over $GF(23)$

Let n be a positive integer with q and n relatively prime. The number of irreducible polynomial factors of $x^n - 1$ over \mathbb{F}_q is equal to the number of cyclotomic cosets of $q \bmod n$ and when:

1) $n = 1$

$x - 1 = x + 22$ is a linear factor.

$x - 1 = x + 22$ is an irreducible polynomial of degree 1 over $GF(23)$.

$C_0 = \{0 \cdot 23^0 \bmod 1\} = \{0\}$ over $GF(23)$

C_0 : Let n be a co-prime to q , the cyclotomic coset of $n \bmod q$ containing i is defined by $C_0 = \{0 \cdot q^j \bmod n \in \mathbb{Z}_n : \{j = 0\}$ C_0 is distiguishable when $C_{j^2}^i = \mathbb{Z}_n$.

- 2) $n = 2$
 $x^2 - 1$; Consider the cyclotomic cosets $23 \bmod 2$ over $GF(23)$:
 $C_i = \{i \cdot 23^j \bmod 2 : j = 0, 1, 2, 3, \dots\}$
 $C_0 = \{0\}, C_1 = \{1\}$
 Therefore, $x^2 - 1$ is a quadratic expression and factorizes into two irreducible linear factors;
 There are only two cyclotomic cosets of $23 \bmod 2$ over $GF(23)$. On the other hand, the number of irreducible polynomials will only be two irreducible polynomials:
 $x^2 - 1 = (x - 1)(x + 1)$
 $= (x + 22)(x + 1)$ over $GF(23)$
- 3) $n = 3$
 $x^3 - 1$; Consider the cyclotomic cosets of $23 \bmod 3$ over $GF(23)$:
 $C_i = \{i \cdot 23^j \bmod 3 : j = 0, 1, 2, 3, \dots\}$
 $C_0 = \{0\}, C_1 = \{1, 2\}$
 Therefore $x^3 - 1$ factorizes into two irreducible factors that divide $x^3 - 1$ over $GF(23)$:
 $x^3 - 1 = (x - 1)(x^2 + x + 1)$
 $= (x + 22)(x^2 + x + 1)$ over $GF(23)$
- 4) $n = 4$
 $x^4 - 1$; Consider the cyclotomic cosets of $23 \bmod 4$ over $GF(23)$:
 $C_i = \{i \cdot 23^j \bmod 4 : j = 0, 1, 2, 3, \dots\}$
 $C_0 = \{0\}, C_1 = \{1, 3\}, C_2 = \{2\}$
 Therefore $x^4 - 1$ factorizes into three irreducible linear factors that is one of degree two and the other two linear factors:
 $x^4 - 1 = (x^2 - 1)(x^2 + 1)$
 $= (x - 1)(x + 1)(x^2 + 1)$
 $= (x + 22)(x + 1)(x^2 + 1)$ over $GF(23)$
- 5) $n = 5$
 $x^5 - 1$; Consider the cyclotomic cosets of $23 \bmod 5$ over $GF(23)$:
 $C_i = \{i \cdot 23^j \bmod 5 : j = 0, 1, 2, 3, \dots\}$
 $C_0 = \{0\}, C_1 = \{1, 2, 3, 4\}$ over $GF(23)$
 There are only two cyclotomic cosets of $23 \bmod 5$ over $GF(23)$
 Therefore the number of irreducible polynomials will be two
 $x^5 - 1 = (x - 1)(x^4 + x^3 + x^2 + x + 1)$
 $= (x + 22)(x^4 + x^3 + x^2 + x + 1)$ over $GF(23)$
- 6) $n = 6$
 $x^6 - 1$; Consider the cyclotomic cosets of $23 \bmod 6$ over $GF(23)$:
 $C_i = \{i \cdot 23^j \bmod 6 : j = 0, 1, 2, 3, \dots\}$
 $C_0 = \{0\}, C_1 = \{1, 5\}, C_2 = \{2, 4\}, C_3 = \{3\}$
 Therefore $x^6 - 1$ factorizes into four irreducible polynomials, two of degree one and two of degree two over $GF(23)$:
 $x^6 - 1 = (x^3 - 1)(x^3 + 1)$
 $= (x - 1)(x^2 + x + 1)(x + 1)(x^2 - x + 1)$
 $= (x + 22)(x^2 + x + 1)(x + 1)(x^2 + 22x + 1)$ over $GF(23)$
- 7) $n = 7$
 $x^7 - 1$; Consider the cyclotomic cosets of $23 \bmod 7$ over $GF(23)$:
 $C_i = \{i \cdot 23^j \bmod 7 : j = 0, 1, 2, 3, \dots\}$

 Therefore $x^7 - 1$ factorizes into three irreducible polynomial factors, one of degree one and two of degree three:
 $x^7 - 1 = (x - 1)(x^6 + x^5 + x^4 + x^3 + x^2 + x + 1)$

$$= (x^2 - 1)(x^2 + 1)(x^4 + 1)$$

$$= (x - 1)(x + 1)(x^2 + 1)(x^4 + 1)$$

$$= (x + 22)(x + 1)(x^2 + 1)(x^2 + 5x + 1)(x^2 + 18x + 1) \text{ over } GF(23)$$

$$x^{10} - 1 = (x^5 - 1)(x^5 + 1)$$

$$= (x - 1)(x^4 + x^3 + x^2 + x + 1)(x + 1)(x^4 - x^3 + x^2 - x + 1)$$

 $(k_1 + 1)(k_2 + 2)(k_3 + 1) \dots (k_m + 1) = \prod_{i=1}^m (k_i + 1)$

3 Conclusion

- 1) Let \mathbb{Z}_q be a given field. If $x^n - 1$ factorizes into a product of linear factors over \mathbb{Z}_q such that $x^n - 1 = (x - 1)^n$ for the number of cyclic codes in

$$R_n = \frac{\mathbb{F}_q[x]}{\langle x^n - 1 \rangle}$$

is given by $n + 1$.

- 2) Let \mathbb{Z}_q be a finite field and $x^n - 1$ be a given cyclic polynomial such that $x^n - 1 = (x - x_1)(x - x_2)(x - x_3) \dots (x - x_n)$ where $x_i \neq x_j \forall i, j$ and suppose that $n = qm$ where $m \in \mathbb{Z}^+$ then, the number of cyclic codes in $R_n = \frac{\mathbb{F}_q[x]}{\langle x^n - 1 \rangle}$ is given by $(q + 1)^k$ where k is the number of distinct factor over \mathbb{Z}_q

- 3) Let \mathbb{Z}_q be a given field and $x^n - 1$ be a given cyclotomic polynomial such that $x^n - 1 = (x - 1)^n$ then the number of irreducible monic polynomials over \mathbb{Z}_q is not equal to the number of cyclotomic cosets.

- 4) Considering the factorizations done in this work and the number of cyclotomic codes generated, we see that the number of cyclic codes over $GF(23)$ is given by

$$n = \begin{cases} 2^k, & \text{if } n \nmid 23 \\ (23 + 1)^k, & \text{if } n = 23m, m \in \mathbb{Z}^+ \\ 23^m + 1, & \text{if } n = 23^m, m \in \mathbb{Z}^+ \end{cases}$$

where k is the number of irreducible factors for $x^n - 1$.
