

# 1 **Impact of foliar application of nutrients on economics of Black gram (*Vigna mungo* L.)**

## 2 **ABSTRACT**

3 The present experiment was laid out at research farm of R.A.K. College of  
4 Agriculture, Sehore (M.P.) during Kharif season of 2022. Results revealed that foliar spray  
5 application of nutrient shows significant effect on yield economics. Treatment T<sub>7</sub> (2% Spray  
6 of DAP + 0.5% Spray of ZnSO<sub>4</sub> at pre-flowering and pod initiation stage) found higher for  
7 yield and yield attributes *i.e.* grain yield (0.834 kg/plot and 7.86 q/ha respectively), silage  
8 yield (17.30q/ha), biological yield (25.16 q/ha), gross return (₹ 62550 ha<sup>-1</sup>), net return ((₹  
9 36491 ha<sup>-1</sup>) and B:C ratio (2.40). While, minimum values found with T<sub>1</sub> (Water spray at pre-  
10 flowering stage and pod initiation stage).

11 **Keywords:** B:C ratio, black gram, economics, foliar spray, yield.

## 12 **Introduction:**

13 Black gram, scientifically known as *Vigna mungo*, is an essential pulse crop within  
14 the legume family that plays a pivotal role in the diets and economics of many countries in  
15 South Asia. It is a vital source of protein and other essential nutrients and holds cultural and  
16 economic significance for the region (Suneja *et al.*, 2011).

17 The United Nations declared the year 2016 as “International Year of Pulses” to  
18 increase the public awareness regarding the nutritional benefits of pulses aimed to improve  
19 food security and nutrition as part of sustainable food production (Mohanty and Satyasai,  
20 2015). The World Health Organization (WHO) recommends 80 g pulse per day per person  
21 and the Indian Council of Medical Research (ICMR) recommends 47g pulse per day per  
22 person. Blackgram consists 22.3% of protein, 48.0% of carbohydrates, 154 mg of calcium,  
23 300 mg phosphorus, 9.1 mg of iron, 1.4 g of 3.37 g of riboflavin, 0.42 g of thiamin and 2 mg  
24 niacin per 100 g of black gram (Asaduzzaman *et al.*, 2010). Though pulses are rich in protein  
25 they are still being cultivated 95 per cent under rainfed condition and more than 78 per cent  
26 under energy starved condition. The main reasons for low productivity of blackgram is poor  
27 nutrient management practices and cultivation under moisture stress condition (Suhathiya and  
28 Ravichandran, 2018). Hence there is a need to increase the production potential of pulses.  
29 The growth phase of blackgram is often obstructed by the slow translocation of assimilates,  
30 poor pod setting due to flower abscission and lack of nutrient during critical stages of crop  
31 growth (Mahala *et al.*, 2001).

32 About 70% of world's black gram production comes from India. In India, its total  
33 area, production and productivity is 4.63 million ha, 2.70 million tones and 570.27 kg/ha  
34 respectively (Agristats, 2022). In India blackgram is very popularly grown in Andhra  
35 Pradesh, Bihar, Madhya Pradesh, Maharashtra, U.P., West Bengal, Punjab, Haryana, and  
36 Karnataka .It is used as nutritive fodder especially for milch cattle. In Madhya Pradesh its  
37 total area, production and productivity is 130.7 lakh ha, 43.937 lakh tonnes and 341 kg/ha  
38 respectively (Anonymous 2022).

39 Foliar application is advantageous than soil application as it is most efficient way to  
40 feed the crop and stimulates root development and increases the resistance of the plant.  
41 Nutrients applied to the foliage are generally absorbed more rapidly and effectively than soil  
42 feeding. Foliar application provides a means of quickly correcting plant nutrient deficiencies,  
43 when identified on the plant. It often provides a convenient method of applying fertilizer  
44 materials especially those which are required in very small amounts and are highly soluble.  
45 When plant nutrients are applied straight to the foliage of plant, smaller quantities of the  
46 fertilizer material are required than when applying to the soil.

#### 47 **Materials and Methods:**

##### 48 **Experimental site**

49 The present experiment was laid out at research farm of R.A.K. College of  
50 Agriculture, Sehore (M.P.) during Kharif season of 2022. The experimental area having fairly  
51 uniform topography, normal fertility status and soil homogeneity.

##### 52 **Climate and weather condition**

53 Sehore is situated in the eastern part of Vindhyan Plateau in subtropical zone at the  
54 latitude of 23.1876° North and longitude of 77.0646° East at 498.77 m above mean sea level  
55 in Madhya Pradesh. The average rainfall varies from 1000 to 1200 mm concentrated mostly  
56 from June to September. The mean annual maximum and minimum temperature are 31.16°C  
57 and 18.50°C, respectively. The summer months are hot and May is the hottest month having a  
58 maximum temperature up to 45.60°C. Winter month experienced mild cold with an average  
59 temperature from 16.56°C to 8.74°C, December is the coldest month as temperature reaches up  
60 to 5°C.

61

62 **Treatment details** T<sub>1</sub>:- Water spray at pre-flowering stage and pod initiation stage, T<sub>2</sub>:- 2%  
 63 Spray of Urea at pre-flowering stage and pod initiation stage, T<sub>3</sub>:- 2% Spray of DAP at pre-  
 64 flowering stage and pod initiation stage, T<sub>4</sub>:- 2% Spray of NPK (18:18:18) at pre-flowering  
 65 stage and pod initiation stage, T<sub>5</sub>:- 0.5% Spray of ZnSO<sub>4</sub> at pre-flowering stage and pod  
 66 initiation stage, T<sub>6</sub>:- 2% Spray of Urea + 0.5% Spray of ZnSO<sub>4</sub> at pre-flowering stage and  
 67 pod initiation stage, T<sub>7</sub>:- 2% Spray of DAP + 0.5% Spray of ZnSO<sub>4</sub> at pre-flowering and pod  
 68 initiation stage, T<sub>8</sub>:- 2% Spray of NPK (18:18:18) + 0.5% Spray of ZnSO<sub>4</sub> at pre-flowering  
 69 and pod initiation stage.

### 70 **Statistical analysis**

71 The data obtained on various parameters were tabulated and subjected to statistical  
 72 analysis by the method suggested by Fisher (1921).

### 73 **Results and Discussion**

#### 74 **Effect of foliar application of nutrients on yield**

75 It was observed from the results that the treatment T<sub>7</sub> (2% Spray of DAP + 0.5%  
 76 Spray of ZnSO<sub>4</sub> at pre-flowering and pod initiation stage) recorded significantly higher grain  
 77 yield (0.834 kg plot<sup>-1</sup> and 786 kg ha<sup>-1</sup> respectively) which was statistically similar with  
 78 treatment T<sub>8</sub> (2% Spray of NPK (18:18:18) + 0.5% Spray of ZnSO<sub>4</sub> at pre-flowering and pod

79 initiation) (0.804 kg plot<sup>-1</sup> and 756 kg ha<sup>-1</sup> respectively) The lowest grain yield was recorded  
80 by treatment T<sub>1</sub> (Water spray at pre-flowering stage and pod initiation stage) i.e. 0.619 kg  
81 plot<sup>-1</sup> and 581 kg ha<sup>-1</sup> respectively. It might be due to constant supply of nutrients due to  
82 foliar spray at reproductive stage of the crop and enhanced the yield components like number  
83 of pods/plant, number of seeds/pod, pod length and 100-seed weight, which had direct  
84 influence on the grain yield. It also might be due to increased uptake of nutrients by black  
85 gram by effective translocation of nutrients from source to reproductive area of crop. The  
86 findings are in agreement with earlier findings of Shashikumar *et al.*, (2013) and Ramesh *et*  
87 *al.* (2016).

88 It might be due to the fact that DAP application contributed towards overall biomass  
89 production under rainfed condition and it also might be due to the enhancement in growth  
90 and yield parameter as well as uptake of nutrients by crop. Obviously, cumulative effects of  
91 these parameters might have contributed to increased grain yield potential of the black gram.  
92 This confirms the finding of Mondal *et al.* (2011), Sritharan *et al.* (2007), Sritharan *et al.*  
93 (2005), Bhowmick *et al.* (2014), Venkatesh *et al.*, (2012), Mondal *et al.*, (2012), Rajavel and  
94 Vincent (2009), Jeyakumar *et al.* (2008) and Malay and Bhowmick (2008). The similar  
95 results are also reported by Anu Lavanya (2011) in green gram, Sengupta *et al.* (2011) in  
96 soybean and Tahir *et al.* (2014) in mash bean.

### 97 **Silage yield**

98 Data on silage yield of black gram is affected by different foliar treatments. silage  
99 yield is directly related with increase in vegetative growth of the plant. It was observed from  
100 the data that the treatment T<sub>7</sub> recorded significantly higher silage yield (17.30 q/ha). The  
101 treatment T<sub>8</sub> (17.18 q/ha) and T<sub>6</sub> (16.54 q/ha) were found at par with treatment T<sub>7</sub> and rest of  
102 treatments found significantly lower straw yield. However, the lowest silage yield was  
103 recorded with treatment T<sub>1</sub> (14.45 q/ha) which was significantly inferior to the rest of the  
104 treatments. The increase in silage yield is directly related mainly to increase in the vegetative  
105 growth of the plant. It might be due to continuous supply of nutrients as basal and as nutrient  
106 spray which in turn increased the leaf area and dry matter accumulation resulting in higher  
107 straw yield. This is also attributed to higher nutrient uptake throughout the crop growth  
108 period. Similar finding is confirmed with the report of Mondal *et al.* (2011), Sritharan *et al.*  
109 (2007), Sritharan *et al.* (2005), Mondal *et al.*, (2012), Rajavel and Vincent (2009) and Malay  
110 and Bhowmick (2008).

## 111 **Biological yield**

112 The biological yield of black gram was significantly affected due to different foliar  
113 nutrition treatments. The foliar nutrition with of treatment T<sub>7</sub> recorded significantly higher  
114 biological yield (25.16 q/ha) which was statistically at par with the treatment T<sub>8</sub> (24.74 q/ha)  
115 and T<sub>6</sub> (23.67 q/ha) and rest of treatments found significantly lower biological yield.  
116 However, the lowest straw yield was recorded with treatment T<sub>1</sub> (20.26 q/ha) which was  
117 significantly inferior to the rest of the treatments. The increased haulm yield might be due to  
118 continuous supply of nutrients which could have increased the leaf area and dry matter  
119 resulting in higher haulm yield (Kuttimani and Velayutham, 2011).

120 **Table 1:- Effect of foliar application of nutrients on grain yield, haulm yield,**  
121 **biological yield and harvest index**

Treatment	Seed yield (Kg plot <sup>-1</sup> )	Seed yield (q/ha)	Silage yield (q/ha)	Biological yield (q/ha)

122

## 123 **Effect of foliar application of nutrients on economics**

### 124 **Cost of Cultivation (₹ . ha<sup>-1</sup>)**

125 Data embodied in Table 2 revealed that other treatment of fertilizers gave more  
126 income over water spray. The highest total cost of cultivation (₹ . 30459 ha<sup>-1</sup>) was incurred  
127 under treatment 2% spray of NPK (18:18:18) + 0.5 % spray of ZnSO<sub>4</sub> at pre-flowering and  
128 pod initiation stage (T<sub>8</sub>) which was higher as compared to all the fertilizer treatments.  
129 Minimum cost of cultivation found in Control treatment (Water spray at pre-flowering stage  
130 and pod initiation stage) i.e. ₹ 24599 ha<sup>-1</sup>.

### 131 **Gross Return (₹ ha<sup>-1</sup>)**

132 It can be interpreted from the data presented in table 2 and **fig 1 that** gross returns  
133 highest response was obtained with 2% Spray of DAP + 0.5% Spray of ZnSO<sub>4</sub> at pre-  
134 flowering and pod initiation stage i.e. ₹ . 62550 ha<sup>-1</sup> followed by 2% Spray of NPK  
135 (18:18:18) + 0.5% Spray of ZnSO<sub>4</sub> at pre-flowering and pod initiation stage (T<sub>8</sub>) (₹ . 60307  
136 ha<sup>-1</sup>). Gross return from water spray at pre-flowering stage and pod initiation stage was ₹  
137 46759 ha<sup>-1</sup> was lower as compared to all the fertilizer spray. These were recorded highest due  
138 to treatment provided better nutritional environment resulted in higher productivity of grain  
139 as well as straw yield.

### 140 **Net Return (₹ ha<sup>-1</sup>)**

141 The data on net return of black gram as influenced by foliar application of different  
142 nutrients has been presented in Table 2 and depicted graphically **in Fig 1** Net return varied  
143 significantly due to foliar application of different nutrients. Net return (₹ . 36491 ha<sup>-1</sup>)  
144 recorded under % Spray of DAP + 0.5% Spray of ZnSO<sub>4</sub> at pre-flowering and pod initiation  
145 stage (T<sub>7</sub>) was found significantly superior than all other treatments and followed by 2%  
146 Spray of Urea + 0.5% Spray of ZnSO<sub>4</sub> at pre-flowering stage and pod initiation stage (₹ .  
147 31753 ha<sup>-1</sup>). While the lowest net return (₹ . 22160 ha<sup>-1</sup>) was obtained in control (water spray  
148 at flower initiation-T<sub>1</sub>). This was due to higher gross return of treatment other than control.  
149 These finding are well supported by the work of Gupta *et al.*, (2011), Deshmukh *et al.* (2008)  
150 and Thakare *et al.* (2006). Similar observations were also recorded by Yakadri and Ramesh  
151 (2002), Chandrasekhar and Bangarusamy (2003), Shashikumar *et al.* (2013), Maheswari and  
152 Karthik (2017).

### 153 **4.4.4 Benefit : Cost**

154 A close analysis of data indicated that Benefit : Cost ratio varied significantly among  
155 foliar application of different nutrients. Highest Benefit : Cost ratio of 2.40 was found out  
156 under 2% Spray of DAP + 0.5% Spray of ZnSO<sub>4</sub> at pre-flowering and pod initiation stage  
157 (T<sub>7</sub>) than all other treatments, followed by 2% Spray of Urea + 0.5% Spray of ZnSO<sub>4</sub> at pre-  
158 flowering stage and pod initiation stage (T<sub>6</sub>), 2% Spray of DAP at pre-flowering stage and  
159 pod initiation stage and 2% Spray of Urea at pre-flowering stage and pod initiation stage.  
160 Lowest Benefit: Cost ratio of 1.90 was found in control plot (water spray at flower initiation-  
161 T<sub>1</sub>). This was due to higher gross return as compare to cost of cultivation. These finding are  
162 well supported by the work of Gupta *et al.*, (2011), Deshmukh *et al.* (2008) and Thakare *et al.*

163 (2006). Similar observations were also recorded by Yakadri and Ramesh (2002),  
164 Chandrasekhar and Bangarusamy (2003), Shashikumar *et al.* (2013), Maheswari and Karthik  
165 (2017).

166 **Table 2:- Effect of foliar application of nutrients on economics of black gram**

Treatment	Cost of Cultivation (₹ ha <sup>-1</sup> )	Gross Return (₹ ha <sup>-1</sup> )	Net Return (₹ ha <sup>-1</sup> )	B:C Ratio
T <sub>1</sub>	24599	46759	22160	1.90
T <sub>2</sub>	24835	54197	29362	2.18
T <sub>3</sub>	25679	56024	30345	2.18
T <sub>4</sub>	30079	51040	20961	1.70
T <sub>5</sub>	24979	52927	27948	2.12
T <sub>6</sub>	25215	56968	31753	2.26
T <sub>7</sub>	26059	62550	36491	2.40
T <sub>8</sub>	30459	60307	29847	1.98

167

## 168 **Conclusion**

169 Blackgram is the most important pulse crop cultivated in India. It is cultivated majorly  
170 under rainfed **condition** in energy starved situation. Hence there is a need to increase the  
171 production potential of blackgram under rainfed condition. From the present investigation  
172 application of 2% Spray of DAP + 0.5% Spray of ZnSO<sub>4</sub> at pre-flowering and pod initiation  
173 stage (T<sub>7</sub>) can be recommended to produce **the** economically sound yield under rainfed  
174 condition.
