

INFESTATION STATUS OF SOME MAJOR INSECT PESTS OF SOYBEAN AND THEIR MANAGEMENT

ABSTRACT

The study was conducted to investigate the effective management of some major insect pests of soybean in the research field of Sher-e-Bangla Agricultural University, Dhaka during the period from December, 2020 to March 2021. The experiment was designed with Randomized Complete Block Design (RCBD) with three replications. During this experiment total six insecticides were tested viz., Lambda-Cyhalothrin @1ml/L of water Neemoil @1ml/L of water with 3g of detergent; Thiamethoxam @0.5g/L of water; Spinosad @0.5ml/L of water; Chlorantraniliprole @0.3ml/L of water; Emamectin Benzoate @1ml/L of water. Data on different pests population number and yield were collected and recorded. The lowest population per unit of whitefly and jassid was found in Emamectin Benzoate @1ml/L of water treated plots after consecutive three times application. Similarly, lowest unit of aphid was found in Chlorantraniliprole @0.3ml/L of water; treated plots. On the other hand, Thiamethoxam @0.5g/L of water were found effective against whitefly, aphid, pod borer per plant, while the highest infestation was observed in control plots. The maximum yield was 1.68 t/ha, observed from Emamectin Benzoate @1ml/L of water, followed by (1.61 t/ha) Chlorantraniliprole @0.3ml/L of water Among the treatments, Emamectin Benzoate @1ml/L of water was more effective for the controlling of insect pests as well as yield of soybean.

Keywords: Soybean, Insecticide, Yield, Whitefly, Aphid, Pod borer, Infestation

INTRODUCTION

Soybean, *Glycine max* (L.) is one of the important oilseed cash crops of the world. It is the largest oilseed crop in the world accounting for more than 45% of the world oilseeds production. It ranks first in the world as edible oil. It is also used in manufacturing several antibiotics, varnishes, adhesives and lubricants and also valuable as protein supplement in human diet and animal feed (Alexander *et al.*1974). The processed soybean is the largest source of protein feed and second largest source of vegetable oil in the world. It has provided 40% protein, well balanced in essential amino acids; 20% oil, rich in polyunsaturated fats specially. Omega 6 and Omega 5 fatty acids; 6-7% total minerals; 5-6% crude fiber and 17-19% carbohydrates In Bangladesh, the present annual production of oilseed and edible oil stands about 373 thousand metric tons and 122 thousand metric tons, respectively. This can satisfy only about 20 percent of the present consumption at 2.9

g/day/head (BBS 2004). Therefore, 80 percent of the requirement of the country is being filled through import. Cultivation of soybean covered about 55,000 hectares of land and produced about 90,000 metric tons of seeds during the period 2009-2010 in Bangladesh (Anonymous 2011). About 380 species of insects have been reported on soybean crop from many parts of the world. About 65 insect species have been reported to attack soybean from cotyledon stage to harvesting stage (Rai et al. 1973). Major insect pest in soybean of national importance are stem fly (*Melanagromyza sojae*), tobacco caterpillar (*Spodoptera litura*), green semiloopers (*Chrysodeixis acuta*), Mealy bug (*Pseudococcus sp.*), girdle beetle (*Obereopsis brevis* Gahan), pod borer (*Helicoverpa armigera*), white fly (*Bemisia tabaci*), leafhopper (*Empoasca kerri*), Aphid (*Aphis sp.*) and pod bug (*Riptortus pedestris*). The defoliators, *S. litura* and *C. acuta* are most damaging pest on soybean (Thippaiah et al. 1997). The full-grown caterpillars are most voracious feeders and cause extensive damage. Because of excessive and indiscriminate use of pesticide several problems like development of resistance in targeted species, resurgence of secondary pest, elimination of natural enemies and wild life. One of the major problems to the successful oilseed production in Bangladesh is the pest infestation. Practical experiences demonstrate that 15 - 20 percent of the total production is lost directly and indirectly by the attack of insect and mite every year. So, integrated management of pests of different oilseed crops is essential for reducing the loss caused by the attack of such pests. Several insecticides present in the market to control pests of soybean, it is necessary to identify the best chemical to control the major insect pests of soybean at an affordable cost and also avoid pest resurgence. Hence, this study was conducted for evaluating the effectiveness of six insecticides for the management of major insect pests of soybean crop. Besides, the current trends of modern society towards 'green consumerism' desiring fewer synthetic ingredients in food may favour plant-based products which are generally recognized as safe in eco-friendly management of plant pests as botanical pesticides (Naik et al. 2012).

MATERIALS AND METHODS

The experiment was carried out at the central farm of Sher-e-Bangla Agricultural University (SAU), Dhaka during the period from December 2020 to March 2021..The study was conducted with seven treatments with three (3) replications. The experiment was laid out in a Randomized Complete Block Design (RCBD). The field was divided into 3 equal sub-plots maintaining 3m x 2m plot size, 0.50 meter block to block distance. 0.75 meter plot to plot distance, where each block was used for each replication and each treatment was randomly assigned in each plot. Plant to plant distance was 20

cm and row to row distance was 30 cm. Each treatment was allocated randomly within the block and replicated three times. Urea, Triple super phosphate (TSP), Muriate of Potash (MP) and Gypsum, . Manures and fertilizers were used as a source of nitrogen, phosphorous, potassium and sulfur respectively with proper intercultural practices. The seven treatments for several soybean pests were, T₁- Lambda Cyhalothrin @ 1ml/L of water at the 15 days intervals;T₂- Neem oil @ 1ml/L of water with 3g of detergent at the 15 days intervals;T₃-Thiamethoxam @0.5g/L of water at the 15 days intervals; T₄- Spinosad @0.5 ml/L of water at the 15 days intervals,T₅- Chlorantraniliprole @0.3ml/L of water at the 15 days intervals;T₆ -Emamectin Benzoate 1ml/L of water at the 15 days intervals andT₇-Untreated Control The recorded data were Number of Whitefly after applying different treatments; Leaf infestation and reduction status of whitefly ;Number of Aphid after applying different treatments; Leaf infestation and reduction status of aphid; Number of Pod borer after applying different treatments; Leaf infestation and reduction status of pod borer; Number of Jassid after applying different treatments; Leaf infestation and reduction status of jassid; Number of healthy leaves and plants; Number of pods per plant; Number of seeds per pod; Number of seeds per plant; Number of seed weight per plant; Yield per plot; Yield per hectare and Increase percentage of yield over control Statistical analysis of data was done with the help of computer software Statistics 10.

RESULTS AND DISCUSSIONS

The present research work was conducted to investigate the effective management of some major insect pests of soybean crop. The management of insect pests of soybean in the fields was evaluated on the basis of the relative efficacy of some insecticides on the mortality and growth inhibition of major insect pests such as whitefly, aphid, pod borer, jassid. Treatments were applied individually with different selected doses. Their effects were evaluated on different parameters viz. unit of pests per plot and yield after applying treatments. The result of different treatments of this experiment has been presented and discussed under the following sub-headings.

4.1.1 Incidence of whitefly after applying treatments (1st, 2nd and 3rd spray of selected insecticides)

From Table 1, before spray, the unit for whitefly per unit in T₁ plot was 2.18, after 1st spray it became 2.01, then a bit decreased after 2nd spray (1.65) and after 3rd sprays (1.55).

For T₂, the unit per unit was 3.03, which decrease after 1st spray (2.83), then a bit reduced after 2nd spray (2.55) and gradually decreased after 3rd spray (2.33), which showed reduction overall for T₂ treatment.

For T₃, the number of whitefly per unit was 1.92 before spray, then the number decreased slightly to 1.67 after 1st spray, the gradually decreased after 2nd (1.32) spray, then became 1.18 due to 3rd spray.

For T₄ treated plots, the unit per unit was 2.65, then the number decreased to 2.42 after 1st spray, then decreased after 2nd (2.35) spray and 3rd (2.13) spray.

In case of T₅, the population was 3.69. After 1st spray, it showed the unit 3.33. The number gradually decreased after 2nd (2.97) and 3rd (2.62) spray.

For T₆, the unit was 1.67 before. The unit of whitefly was 1.45, 1.26 and 1.05 for 1st, 2nd and 3rd application respectively. This treatment showed significant reduction for population.

For T₇, the unit was 4.13 after 1st, 2nd and 3rd spray; it became 4.39, 4.53 and 4.69 respectively from Table 1.

number of whitefly per unit was recorded and statistically significant variations were observed among the treatments applied for controlling major insect pests of soybean. Results showed that after 1st, 2nd, 3rd spray, the lowest number of whitefly was recorded in T₆ treated plot, which was statistically similar with T₃ treatment; whereas the highest number was recorded in T₇ treatment and which was closely followed by T₅.

As a result, the order of rank of study the effect of different management on the incidence of major insect pest of soybean by number was T₆> T₃> T₁> T₄> T₂> T₅> T₇. So, T₆-Emamectin Benzoate 1ml/L of water was considered best.

Table 1: Incidence of whitefly after applying treatments at the different spray times

Treatment	No. of whitefly per unit			
	Before spray	After 1 st spray	After 2 nd spray	After 3 rd spray
T ₁	2.18	2.01 de	1.65 cd	1.55 cd
T ₂	3.03	2.83 c	2.55 b	2.33 bc
T ₃	1.92	1.67 e	1.32 d	1.18 d
T ₄	2.65	2.42 cd	2.35 bc	2.13 bc
T ₅	3.69	3.33 b	2.97 b	2.62 b
T ₆	1.67	1.45 e	1.26 d	1.05 d

[In column, means containing same letter(s) indicate significantly similar under LSD at 5% level of significance. Values are the means of three replications.]

[T₁- Lambda Cyhalothrin @ 1ml/L of water at the 15 days intervals; T₂- Neem oil @ 1ml/L of water with 3g of detergent at the 15 days intervals; T₃-Thiamethoxam @0.5g/L of water at the 15 days

intervals; T₄- Spinosad @0.5 ml/L of water at the 15 days intervals; T₅- Chlorantraniliprole @0.3ml/L of water at the 15 days intervals; T₆-Emamectin Benzoate 1ml/L of water at the 15 days intervals and T₇-Untreated Control]

4.1.2 Leaf infestation status and reduction over control percentage of Whitefly

A significant variation was also observed due to the effect of different chemicals and botanical management of insect pests on soybean plant in respect of number of whitefly per plant unit. The minimum infestation percentage was found at T₆ treated pot (9.6%), where the reduction over control percentage (61.6 %) was found the highest also. On the other hand, the maximum infestation percentage was recorded from control treatment (T₇) and the lowest % of reduction over control (40.76%) was observed in T₁ treated plot (Figure 1).

Figure 1: Effect of different management practices on the leaf infestation and reduction over control percentage of whitefly

4.2.1 Incidence of Aphid after applying treatments

From Table 2, in context of aphid, after 1st spray, the lowest number of aphid unit was recorded in T₅ (1.60) treated plot and closely followed by T₃ (1.93), T₁ (2.01), T₄ (2.57) T₆ (2.65), T₂ (2.73) treatments; whereas the highest number was recorded in T₇ (3.74). In this case, T₃ (1.93) was statistically similar with T₁ (2.01) treatment.

In case of 2nd spray, the unit per unit was lowest in T₅ (1.45) treated plot, which was statistically similar with T₃ (1.68) and T₁ (1.78) treatments. The highest unit was in T₇ (3.98) and closely followed by T₂ (2.58) treatment.

After final spray, the lowest population per unit was found in the plot treated with T₅ (1.34), which was statistically similar with T₃ treatment and the unit was 1.49; whereas the highest number was recorded in T₇ (4.03) treatment and closely followed by T₂ (2.41) treatment.

Before spray, the unit for T₁ plot was 2.19, which reduced after 1st spray (2.01) and decreased after 2nd spray (1.78) and 3rd spray (1.57).

For T₂, the unit was 3.12, which increase after 1st spray (2.73), then reduced after 2nd spray (2.58) and gradually decreased after 3rd spray (2.41), which showed reduction overall for T₂ treatment.

For T₃, the number of aphid was 2.18 before spray, then the number decreased slightly to 1.93 after 1st spray, the gradually decreased after 2nd (1.68) spray and 3rd spray. (1.49)

For T₄ treated plots, the unit was 2.73 before. The unit of aphid was 2.57, 2.38 and 2.14 for 1st, 2nd and 3rd application respectively.

In case of T₅, the unit was 1.85, then the number decreased to 1.60 after 1st spray, then also decreased after 2nd (1.45) spray and 3rd (1.34) spray.

For T₆, the population was 2.97. After 1st spray, unit was 2.65. The number gradually decreased after 2nd (2.43) and 3rd (2.27) spray.

For T₇, the unit was 3.45. After 1st, 2nd and 3rd spray, it became 3.74, 3.98 and 4.03 respectively in Table 2.

As a result, the order of rank of study the effect of different management on the incidence of major insect pest of soybean by number was T₅> T₃> T₁> T₄> T₆> T₂> T₇.

Table 2: Incidence of Aphid after applying treatments at the different spray times

Treatment	No. of aphid per unit			
	Before spray	After 1 st spray	After 2 nd spray	After 3 rd spray
T ₁	2.19	2.01 c	1.78 c	1.57 c

[In column, means containing same letter indicate significantly similar under LSD at 5% level of significance. Values are the means of three replications.]

[T₁- Lambda Cyhalothrin @ 1ml/L of water at the 15 days intervals; T₂- Neem oil @ 1ml/L of water with 3g of detergent at the 15 days intervals; T₃-Thiamethoxam @0.5g/L of water at the 15 days intervals; T₄- Spinosad @0.5 ml/L of water at the 15 days intervals; T₅- Chlorantraniliprole @0.3ml/L of water at the 15 days intervals; T₆-Emamectin Benzoate 1ml/L of water at the 15 days intervals and T₇-Untreated Control]

4.2.2 Leaf Infestation Status and Reduction Over Control Percentage of Aphid

A significant variation was also observed due to the effect of different chemicals and botanical management of pest on soybean plant in respect of number of aphid per leaf. The minimum infestation percentage was found at T₅ treated pot (9.7%), where the reduction over control percentage (65.35 %) was found the highest also. On the other hand, the maximum infestation percentage (28%) was recorded from control treatment (T₇) and the lowest % of reduction over control (50 %) was observed in T₂ treated plot (Figure 2).

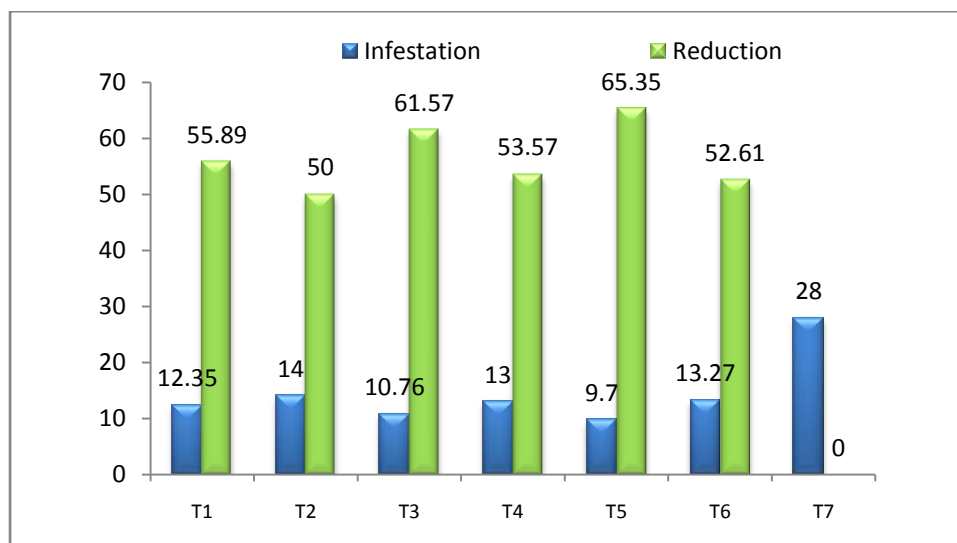

Figure 2: Effect of different management practices on the leaf infestation and reduction over control percentage of aphid

4.3.1 Incidence of Jassid after applying treatments at the different spray times

From Table 3, the results of treatments showed that after 1st spray, the lowest number of jassid was recorded in T₆ (1.46) treated plot, which was statistically similar with T₁ (1.57). The highest number was recorded in T₇ (3.34) treatment and closely followed by T₅ (2.62).

In case of 2nd spray, the unit was lowest in T₆ (1.33) treated plot and closely followed by T₁ (1.35), T₃ (1.58), T₂ (1.74), T₄ (2.09) and T₅ (2.35) treatments. The highest unit was in T₇ (3.67). Here, T₁ (1.35) and T₃ (1.58) both were statistically similar.

After final spray, the lowest population was found in the plot treated with T₆ treatment and the unit was 1.10 and closely followed by T₁ (1.26), T₃ (1.37), T₂ (1.67), T₄ (1.89) and T₅ (2.07). The highest number was recorded in T₇ (3.79) treatment.

Before spray, the unit for T₁ plot was 1.87, which decreased after 1st spray (1.57), a bit fell after 2nd spray (1.35) and 3rd spray (1.26).

For T₂, the unit was 2.29, which increase after 1st spray (2.11), then reduced after 2nd spray (1.74) and gradually decreased after 3rd spray (1.67).

For T₃, the number of jassid was 2.06 before spray, then the number decreased slightly to 1.89 after 1st spray, the gradually decreased after 2nd (1.58) spray and 3rd spray (1.37).

For T₄ treated plots, the unit was 2.48, then the number decreased to 2.26 after 1st spray, then increased after 2nd (2.09) spray and decreased drastically after 3rd (1.89) spray.

In case of T₅, the population was 2.97. After 1st spray, it showed reduction of unit 2.62. The number decreased after 2nd (2.35) and 3rd (2.07) spray.

For T₆, the unit was 1.82 before. The unit of jassid was 1.46, 1.33 and 1.10 for 1st, 2nd and 3rd application respectively.

For T₇, the unit was 3.19. After 1st, 2nd and 3rd spray, it became 3.34, 3.67 and 3.79 respectively in table 3.

As a result, the order of rank of study the effect of different management on the incidence of major insect pest of soybean by number was T₆> T₃> T₁> T₂> T₄> T₅> T₇.

Table 3: Incidence of Jassid after applying treatments at the different spray times

Treatment	No. of jassid per unit			
	Before spray	After 1 st spray	After 2 nd spray	After 3 rd spray

4.3.2 Leaf infestation status and reduction over control percentage of Jassid

A significant variation was also observed due to the effect of different chemicals and botanical management of pest on soybean plant in respect of number of whitefly per leaf. The minimum infestation percentage was found at T₆ treated pot (9.9 %), where the reduction over control percentage (65.35 %) was found the highest also. On the other hand, the maximum infestation percentage was recorded from control treatment (T₇) and the lowest % of reduction over control (50 %) was observed in T₆ treated plot (Figure 3).

Figure 3: Effect of different management practices on the leaf infestation and reduction over control percentage of jassid

4.4.1 Incidence of Pod borer after applying treatments

From Table 4, Considering pod borer, before and after 1st spray, there was no sign of this pest, as it is only available in the reproductive stage.

In case of 2nd spray, the unit was lowest in T₁ (1.19) treated plot, which was statistically similar with T₄ (1.42) treatment. The highest unit was in T₇ (2.19) and closely followed by T₆ (2.04) treatment.

After final spray, the lowest population was found in the plot treated with T₁ (0.78), which was statistically similar with T₄ (0.92) treatment. The highest unit was in T₇ (1.64), which was statistically similar with T₆ (1.56) treatment.

As a result, the order of rank of study the effect of different management on the incidence of major insect pest of soybean by number was T₄> T₁> T₃> T₅> T₂> T₆> T₇.

Table 4: Effect of define treatments on the number of Pod borer, number of healthy and infested pods/Plant due to pod borer of soybean

4.4.2 Pod Infestation Status and Reduction over Control Percentage of Pod Borer

A significant variation was also observed due to the effect of different chemicals and botanical management of pest on soybean plant in respect of number of Pod borer/Plant. The minimum infestation percentage was found at T₁ treated pot (10.62%), where the reduction over control percentage (55.75%) was found the highest. On the other hand, the maximum infestation

percentage was recorded from control treatment (T₇) and the lowest % of reduction over control (47.75 %) was observed in T₆ treated plot (Figure 4).

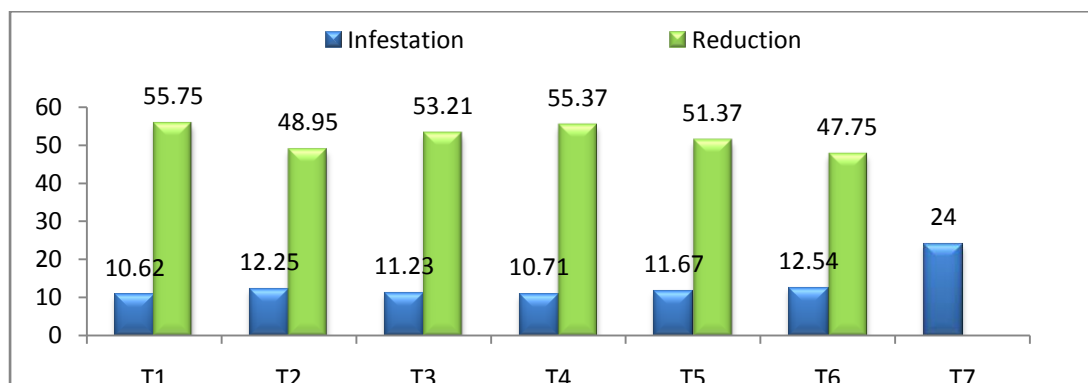

Figure 4: Effect of different management practices on the pod infestation and reduction over control percentage of pod borer

4.5 Effect of different spray times of selected insecticides on healthy and infested leaves/plant, % of Infestation due to insect pests of soybean

From Table 5, results showed that the highest percentage of leaves per plants infestation was recorded in T₇ (83.9) treated plot and closely followed by T₂ (25.18), T₁ (22.52), T₃ (18.39), T₄ (17.97) and T₅ (9.05) treatments, whereas the lowest number was recorded in T₆ (6.83) treatment. The percent reduction over control was maximum in T₆ (91.86 %) and minimum in case of T₁ (68.28%).

Table 5: Effect of different spray times of selected insecticides on healthy and infested leaves/plant, % of Infestation due to insect pests of soybean

Treatment (s)	Healthy leaves	Infested leaves	%Leaf infestation	%Reduction over control

4.6 Effect of different spray times of selected insecticides on healthy and infested plants/ plot, % of Infestation due to insect pests of soybean

Results showed that the highest percentage of plants infestation per plot was recorded in T₇ (75.39) treated plot, which was statistically similar with T₂ (49.94); whereas the lowest number was recorded in T₆ (23.07) treatment and closely followed by T₄ (33.64) treatments. The percent reduction over control was maximum in T₆ (69.40 %) and minimum in case of T₂ (33.76 %) from Table 6.

Table 6: Effect of different spray times of selected insecticides on healthy and infested plants/plot, % of Infestation due to insect pests of soybean

[T₁- Lambda Cyhalothrin @ 1ml/L of water at the 15 days intervals; T₂- Neem oil @ 1ml/L of water with 3g of detergent at the 15 days intervals; T₃-Thiamethoxam @0.5g/L of water at the 15 days intervals; T₄- Spinosad @0.5 ml/L of water at the 15 days intervals; T₅- Chlorantraniliprole @0.3ml/L of water at the 15 days intervals; T₆-Emamectin Benzoate 1ml/L of water at the 15 days intervals and T₇-Untreated Control]

4.7 Effect of treatments on soybean yield after applying treatments at the different spray times (1st, 2nd and 3rd spray of selected insecticides)

In table 7, results showed that the highest number of pod per plant (39.41) was recorded in T₆ treated plot, which was statistically similar with T₅ (37.33). On the other hand, the lowest number was recorded in T₇ (29.81) treatment and closely followed by T₂ (31.43). The highest number of seed per pod (3.00) was recorded in T₆ treated plot, whereas the lowest number was recorded in T₇ (2.7) treatment. The highest number of seed per plant (118.23) was recorded in T₆ treated plot, whereas the lowest number was recorded in T₇ (80.49) treatment. The highest number of seed weight per plant (15.42) was recorded in T₆ treated plot, whereas the lowest number was recorded in T₇ (9.06) treatment.

Table 7: Effect of different spray times of selected insecticides on yield attributes and yield of Soybean

Treatment	Pod/ Plant	No. of seed / pod	No. seeds /plant	Wt. of seeds/ plant	Wt. of 100 seeds (g)
T ₁	33.39 cd	3.0 a	100.17 c	12.25 d	12.23 b

4.7.1 Yield of soybean per plot

Figure 5: Effect of different management practices on the yield (kg/plot) of soybean

4.7.2 Yield of Soybean per hectare

Yield of soybean per hectare was significantly affected by the application of different insecticide. As a result Emamectin Benzoate @1ml/L of water showed the highest yield (1.68 t/ha). On the other hand, the lowest yield (0.88 t/ha) was found control treatment (Fig.6). From the above results, it was found that the among all applied insecticide treatments in this study, Emamectin Benzoate @1ml/L of water showed the better performance in reducing the pest as well as on increasing yield of soybean.

Figure 6: Effect of different management practices on the yield (t/ ha) of soybean

4.7.3 Correlation between Yield (ton/ha) and % Infestation due to insect pests of soybean

Correlation study was done to establish the relationship between percent of plant infestation/treated plot and healthy fruit yield (ton/ha) among different management practices. From the Figure 7, it was revealed that positive correlation was observed between the parameters. It was evident that the equation $y = -0.015x + 2.036$ gave a good fit to the data and the co-efficient of determination ($r^2 = 0.829$) fitted regression line had a significant regression co-efficient. It may be concluded from the figure that the healthy fruit yield was strongly as well as negatively correlated with percent of plant infestation/treated plot. Fruit yield (ton/ha) was decreased due to increase of the percent of plant infestation/treated plot.

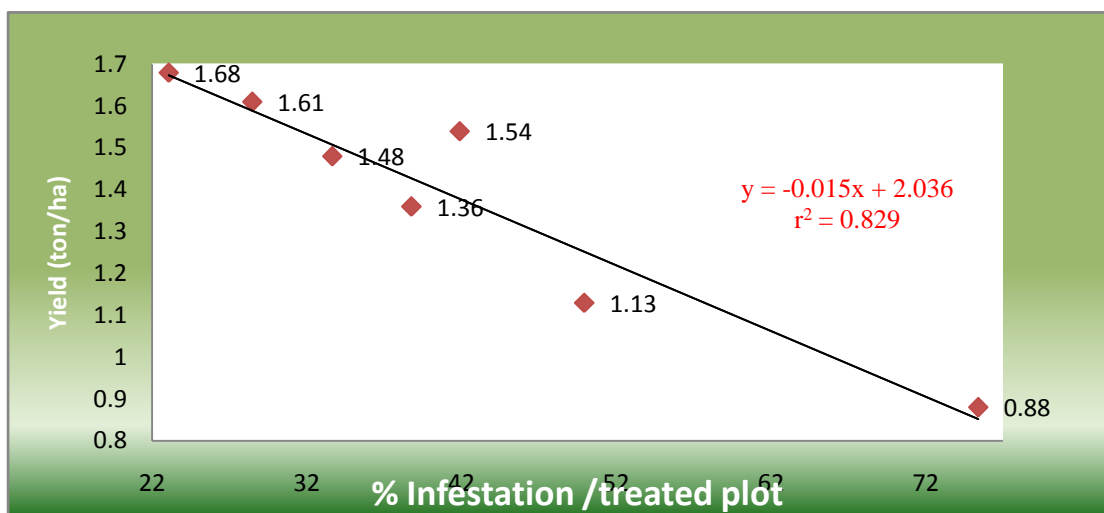

Figure 7: Effect of different management practices on the correlation between yield and infestation of soybean

4.7.4 Correlation between Yield (ton/ha) and % Increase over control due to insect pests of soybean

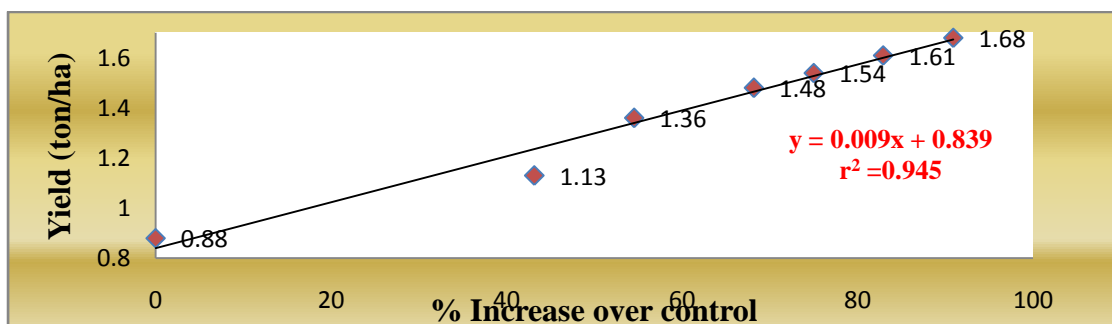

Figure 8: Effect of different management practices on the correlation between yield and % increase yield over control of soybean

Correlation study was done to establish the relationship between percent (%) increase yield over control of soybean /treated plot and healthy fruit yield (ton/ha) among different management practices. From the Figure 8, it was revealed that positive correlation was observed between the parameters. It was evident that the equation $y = 0.009x + 0.839$ gave a good fit to the data and the co-efficient of determination ($r^2 = 0.945$) fitted regression line had a significant regression co-efficient. It may be concluded from the figure that the healthy fruit yield was strongly as well as positively correlated with percent (%) increase yield over control of soybean /treated plot. Fruit yield (ton/ha) was decreased due to increase of the percent of plant infestation/treated plot.

Considering the results of the experiments the efficacy of different treatments for the management of major insect pests in soybean as controlling components were in order as:

Emamectin Benzoate 1ml/L of water > Chlorantraniliprole @0.3ml/L of water > - Spinosad @0.5 ml/L of water > Lambda Cyhalothrin @ 1ml/L of water > Thiamethoxam @0.5g/L of water > Neem oil @ 1ml/L of water

The effectiveness of different treatments obtained in the present investigation is in agreement with the results obtained by Venkataiah(2020), Wadnekar (2004), Joshi (2010), Patil (2015) and Thanushya (2011). According to Venkataiah *et al.* (2020) the chemical insecticide Emamectin benzoate 5% SG@ 0.5 g/l found effective in controlling population, to reduce leaf damage and pod infestation also produce the maximum grain yield. Wadnekar *et al.* (2004) reported that, unit of aphid (0.4, 0.83 and 1.17aphids/leaf after 2, 7 and 14 DAS, respectively) was found to be significantly low in thiamethoxam 25 WG @ 150 g a.i/ha. Emamectin benzoate @ 5 gm/10 litre were most effective for the control of jassid (Joshi *et al.* 2010). Lambda cyhalothrin and spinosad both are considered effective (Thanushya *et al.* 2011). Patil *et al.* (2015) also found that emamectin benzoate 1.9 EC at the rate of 200 ml per ha and indoxacarb 14.5 SC at the rate of 500 ml per ha obtained higher yield of soybean.

In the present study, the results obtained are very encouraging and there is a great potential for the use of emamectin benzoate 1ml/L of water as a toxic agent in soybean pests management systems in our country, although, the result obtained in this study may differed from those of the other workers.

CONCLUSION

The incidence of whitefly was found lowest in T₆ treated plot, which was statistically identical with T₃ treatment after different spray times. Besides, the infestation status and reduction control were also recorded most effective for T₆ treatment.

In context of aphid, after different spray times, the lowest number of aphid was recorded in T₅ treated plot, which was statistically identical with T₃ treatment. I also found that, the infestation status and reduction control were also recorded most effective for T₅ treatment.

Considering the incidence of pod borer was found lowest in T₄ treated plot, which was statistically identical with T₁ treatment after different spray times. Besides, the infestation status and reduction control were also recorded most effective for T₄ treatment.

Now, the lowest jassid population was recorded in T₆ and T₁ after different spray times. Besides, the infestation status and reduction control were also recorded most effective for T₆ treatment.

The minimum percent of both leaf and plant infestation were recorded in T₆ treated plots.

In case of pod number, the highest number and lowest number was recorded in T₆ and T₇

Similarly, the maximum and minimum number of yield was recorded in T₆ (1.01 kg/ plot and 1.68 t/ha) and T₇ (0.53 kg/plot and 0.88 t/ha) respectively. Finally, the highest percentage of yield increase over control was found in T₆ (90.91 %) than other treatments.

From the study of the following conclusions may be drawn that, among the treatments, T₆ (Emamectin Benzoate @1ml/L of water) was more effective for the controlling of whitefly, Jassid as well as low infestation, highest pod number, seed number and yield of Soybean. On the other hand, the T₃ (Thiamethoxam @0.5g/L of water) treatment was effective for reducing the population of whitefly and aphid. Lastly, the T₁ (Lambda-Cyhalothrin @1ml/L of water) treatment was suitable for only pod borer.
