

Minireview Article

A systematic review on Management of condylar fracture

ABSTRACT

AIM: The mandibular condyle or sub condylar region is one of the most frequent site of mandibular fracture encountered, occurring between 25% and 35% of all mandibular fractures. Condyle fracture accounts for approximately 30% and 37% of fracture in dentulous mandible patients and edentulous mandible patients, respectively. Surgeons often debate on which type of plate has a better potency over the other for the fixation of condylar fracture. We have tried to resolve this by conducting a systematic review by comparing the reduction outcomes of using 2 mini plates and 1 trapezoidal plate for condylar fractures.

MATERIALS AND METHODS: An elaborate data base was done to collect articles pertaining to Fixation of condylar fracture using trapezoidal or mini plate. The study selection was restricted to articles published in English and from the year 1984 to 2021. The review was done in accordance with Preferred Reporting

Items for Systematic Reviews and Meta-Analysis (PRISMA) statement guidelines after detailed PICO analysis.

RESULTS: The initial search returned 300 studies reported from January 1984 through June 2021. Abstract and full-text reports were acquired for 20 studies.

After reviewing the full-text reports on the basis of inclusion/ exclusion criteria, Amster 2 scale, Pedro Scale and Robis only 2 studies were deemed eligible for the present review. The total sample size was 70 patients including 56 males and 14 females with mandibular sub condylar fractures and other concomitant fractures.

The patients were classified in two groups according to the fixation method. The 2 fixation methods used are mini plates (group A) or a trapezoidal plate (group B).

CONCLUSION: The results of the systematic review concluded that that both the plates perform equally in the grounds of fracture reduction, functionally stable fixation, and postoperative infection and condylar movements. But trapezoidal plates are superior in terms of stability, hardware failure and time taken for fixation.

Keywords : condylar fracture, Mini Plates, Trapezoidal plate, Comparison

INTRODUCTION

The mandibular condyle or sub condylar region is one of the most frequent site of mandibular fracture encountered, occurring between 25% and 35% of all mandibular fractures. Condyle fracture accounts for

approximately 30% and 37% of fracture in dentulous mandible patients and edentulous mandible patients, respectively ^[1]. There are various treatment options available for fixation of condylar fractures. Open reduction has now become a popular choice as it provides more accurate anatomic reduction, lesser time on inter maxillary fixation which improves patient compliance and therefore more successful outcomes. The choice of plate helps in reduction and fixation of the fracture. Various fixation plates are available, the most commonly used plates for fixation of condylar fractures are trapezoidal, delta, strut and mini plate.

PICTURE 1: Trapezoidal plate

Sub condylar fracture can be reduced by using a single or double mini plate. Double mini plates provide better 3 dimensional stability to the fracture as compared to single mini plate when screwed along the Champy's line of osteosynthesis.

PICTURE 2: 2 mini plate

Trapezoidal plate is a 3 – D plate used in the anatomically constricted region of condylar neck. One arm of the plate is placed parallel to condylar axis and to the mandibular notch. Therefore it simulates how two mini plates function in the treatment of condylar fracture ^[2].

PICTURE 3: 2 non parallel mini plate for Condylar fracture reduction and fixation

PICTURE 4: Trapezoidal plate for condylar fracture reduction and fixation

Sheng Yao et al in his study quotes that the major components that standardizes healing of condylar fracture are : (1) mouth opening greater than 40 mm, (2) had no pain, (3) mandible had good activity in all directions, (4) patients who had recovered their occlusal relationship before injury, (5) temporomandibular joint stability, and (6) symmetric facial appearance.^[4] In this systematic review a comparison between trapezoidal and mini plates is being done to evaluate which plate is better for the treatment of condylar fractures. These two plates were chosen for this study as they are the most commonly used plates for the fixation of mandibular fractures.

METHODOLOGY

An elaborate data base search using search engines like google scholar, Pub med, Ebsco Host, Medline, Cochrane library and EMBase was done to collect articles pertaining to Fixation of condylar fracture using

trapezoidal or mini plate. The study selection was restricted to articles published in English and from the year 1984 to 2021. The review was done in accordance with Preferred Reporting Items for Systematic Reviews and Meta-Analysis (PRISMA) statement guidelines after detailed PICO analysis. The following were the Pico components

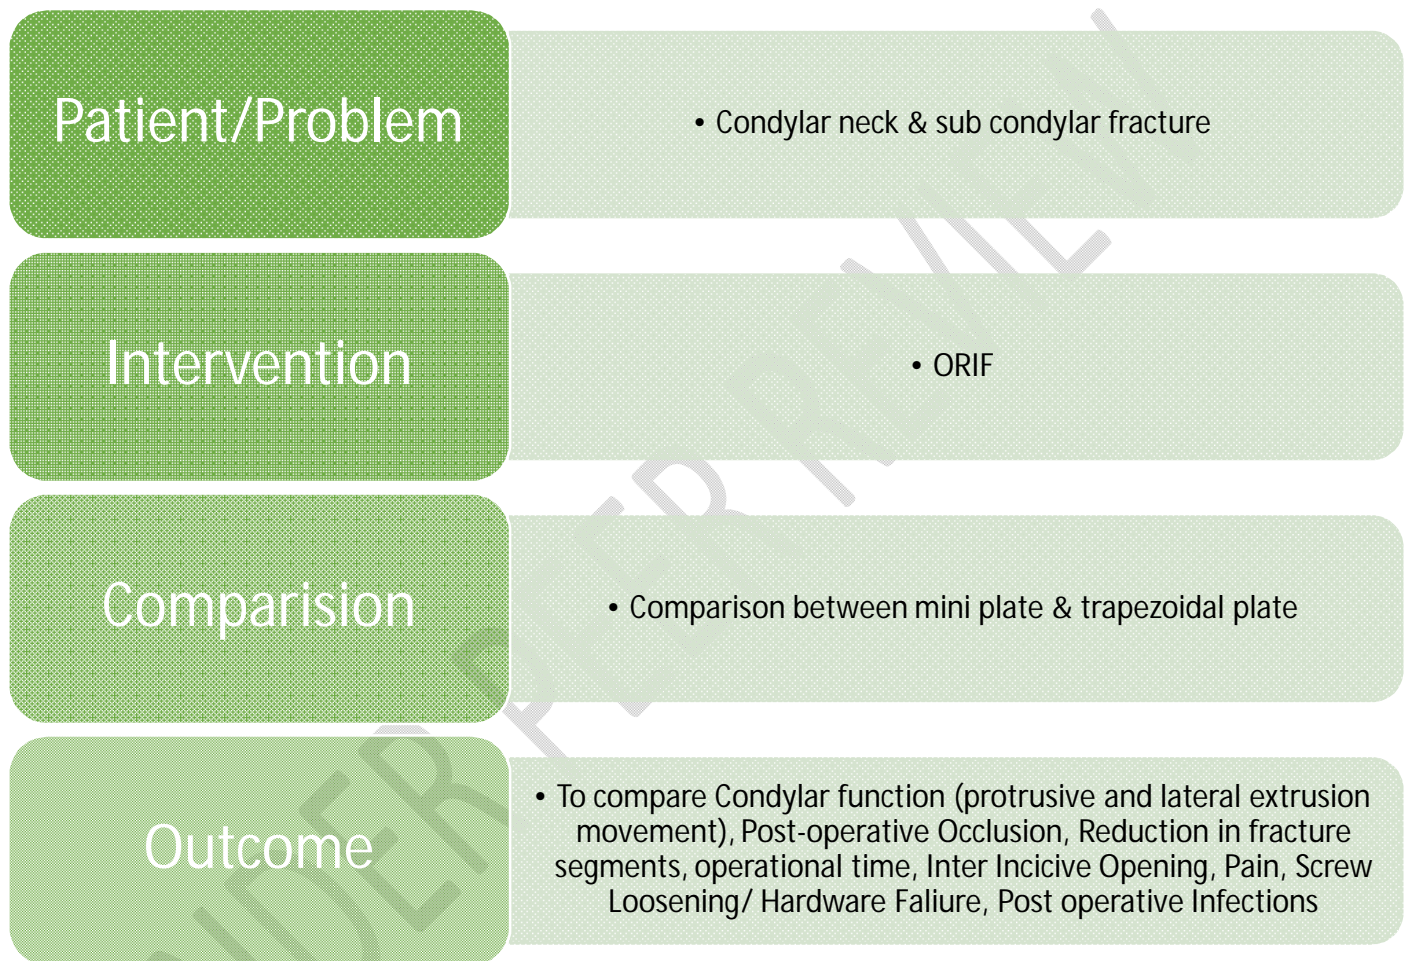

Fig .1 : Study protocol

Boolean terms such as Internal fixation AND 'mandibular condylar fracture; One miniplate compared with two AND mandibular condylar fracture; Single miniplate compared with double miniplate AND mandibular condylar fracture; Mandibular condylar fracture AND Trapezoidal plate; Clinical and radiological outcomes AND mandibular condylar fracture and treatment outcomes AND mandibular condylar fractures; Mini plate AND condylar fracture; Mini plate AND trapezoidal plate AND condylar

fracture. Initial article selection as done on the basis of preset inclusions which were Studies of humans. Adult patients with mandibular condylar fracture treated with open reduction and internal fixation. Fixation done using mini plate or trapezoidal plate. And exclusion criteria were set as Literature reviews, brief case reports, abstract-only reports, and reports written in a language other than English, Studies performed using animal mandibles, Lab studies done on polyurethane or other models, Studies that had evaluated degradable fixation systems, Studies that had used no titanium plates and screws, Studies in which fixation of the fracture was completed with wires or screws alone were excluded, Communitied fractures, Patient requiring bone graft, Syndromic patients with condylar fracture, Edentulous patients with condylar fracture. After the initial selection, careful reviewing of the full text was done to extract information on the following criteria

1. Condylar function – It was evaluated by the operator by observing protrusive and lateral extrusion movement of the mandible.
2. Post-operative Occlusion - Checked by maximum intercuspation of teeth between both the arches
3. Reduction in fracture segments – Evaluation was done on regular follow ups 1 month postoperatively by radiographs
4. Hardware failure or screw loosening - Was checked on regular follow ups 1 month postoperatively by radiographs
5. Operation time was measured by time taken to reduce and fix fracture with plates.
6. Maximum interincisal opening was measured using a ruler postoperatively.
7. Pain was measured by using a visual analogue scale on a range of 1 – 100.

The quality, strength and risk of bias of various study was evaluated by using AMSTAR – 2, after which data collection was done in tabular form using Microsoft Excel for further interpretation

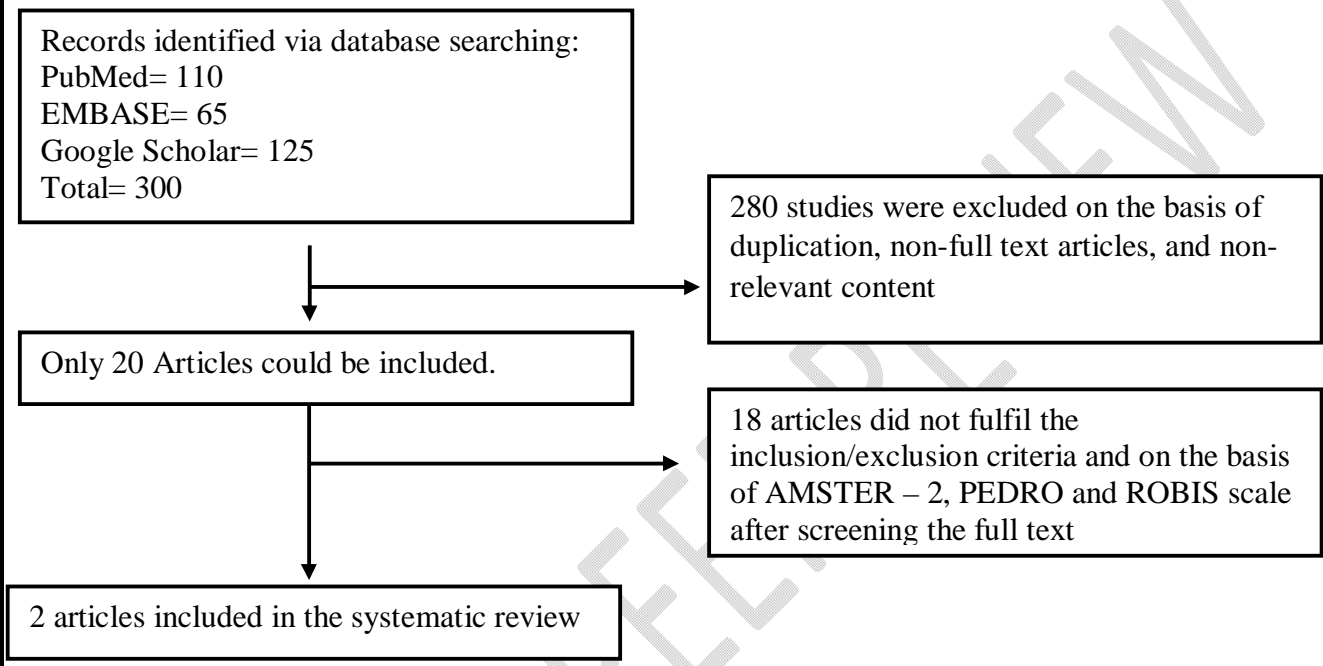

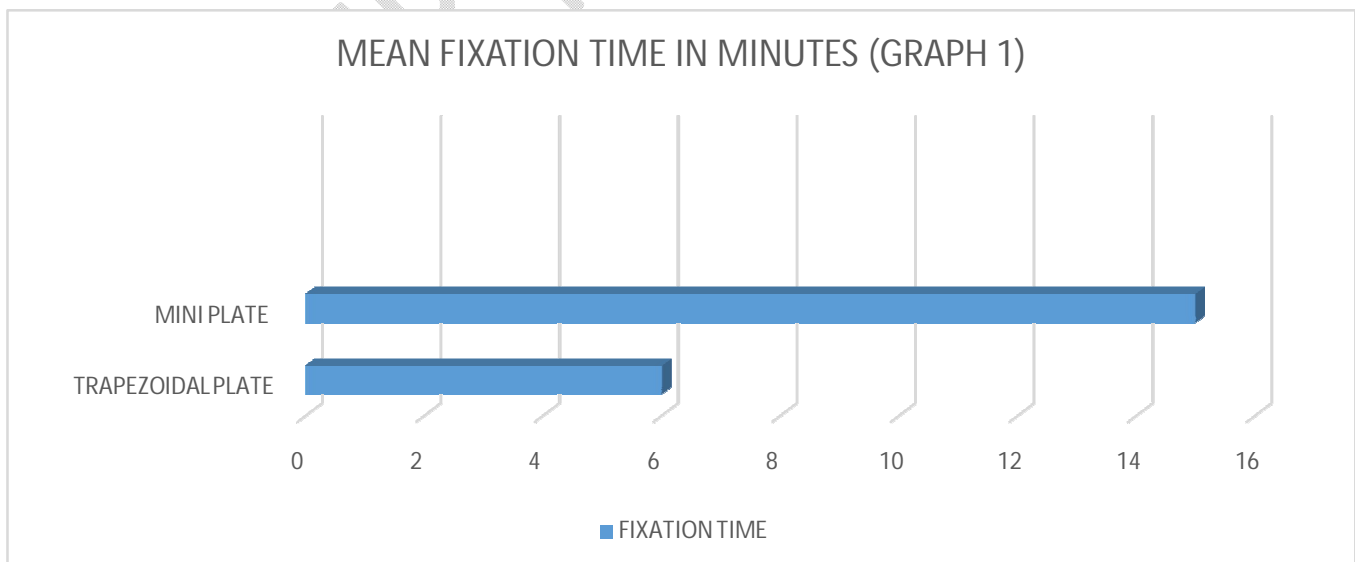

Fig.2 : Study principles and database searching

RESULT

The initial search returned 300 studies reported from January 1984 through June 2021. Abstract and full-text reports were acquired for 20 studies. After reviewing the full-text reports on the basis of inclusion/exclusion criteria, Amster 2 scale, only 2 studies were deemed eligible for the present review. Primary data was extracted from 2 included studies. The total sample size was 70 patients including 56 males and 14 females with mandibular sub condylar fractures and other concomitant fractures. The most prevalent etiology was RTA (70%) followed by fall, assault and sport injury. The patients were classified in two groups according to the fixation method. The 2 fixation methods used are mini plates (group A) or a trapezoidal plate (group B).

1. Operation time

The operational time was significantly shorter for fixation using trapezoidal plate than 2 mini plates. The mean time taken for fracture reduction and fixation for trapezoidal plate was 6 mins (3- 26 mins) whereas for mini plate fixation the time taken was 15 mins (6 – 60 mins). (GRAPH 1)

2. Reduction in fracture

The anatomic reduction the fracture segments did not yield much difference in both the groups.

This was evaluated by using radiographs by the operator. Both the plates provided adequate reduction for the fracture segments.

3. Occlusion

The occlusion was checked by maximal intercuspation of teeth .In both the groups as reported by the authors no patient reported back with the complaint of occlusal derangement or instability which warranted a second surgery. However mild occlusal disharmonies were managed by grinding.

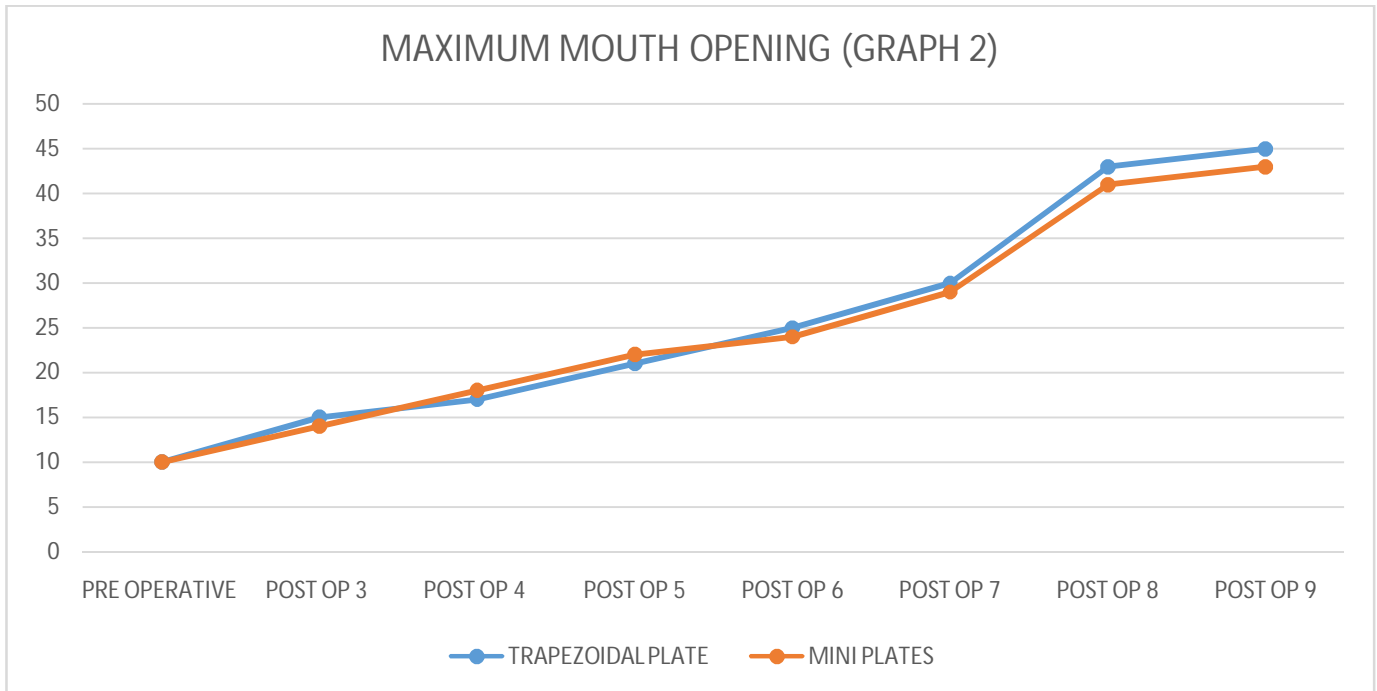

4. Condylar movements

There was decreased immediate postoperative condylar movement mostly protrusive and lateral excursion movements which subsequently improved in the post-operative follow up.

5. Inter incisal opening

The immediate postoperative mean inter incisal distance was noted to be 15 mm (10 – 20 mm).

Interincisal opening was not significantly different in both the groups. (GRAPH. 2)

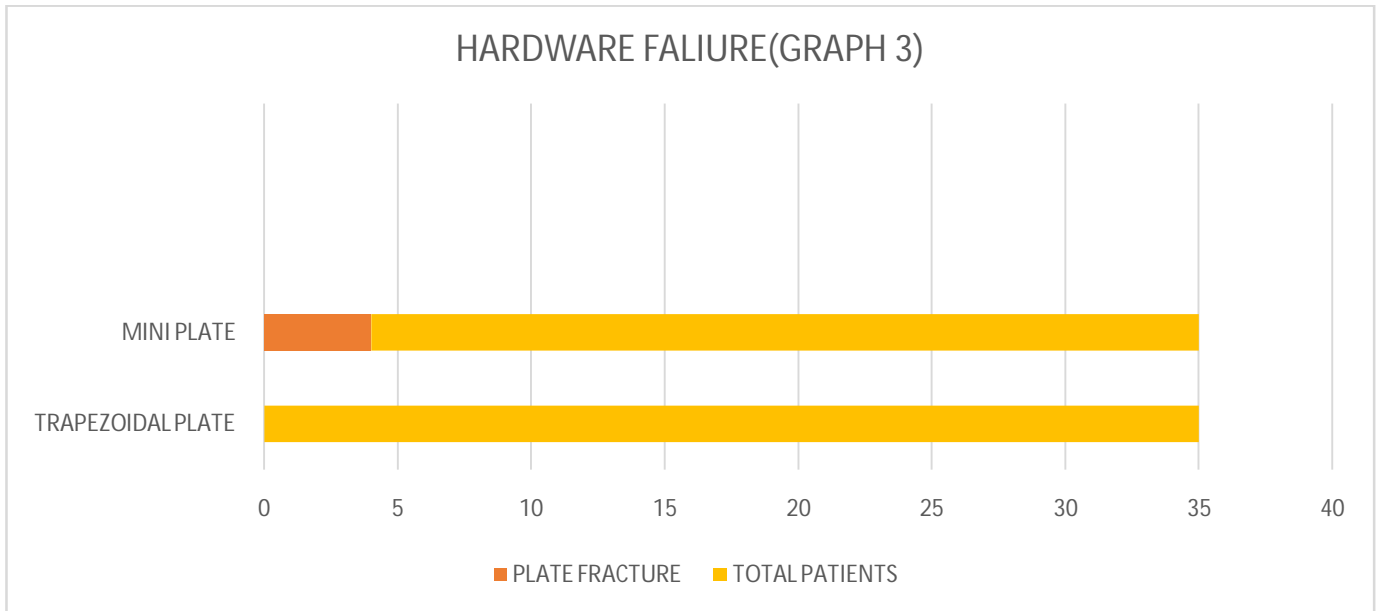

6. Pain

Pain was observed in patients immediately after surgery and also in cases of plate fracture. The pain could also be due to the surgery. A mean value of 33.33 was observed in both the cases which subsided eventually in further recalls.

7. Screw loosening / hardware failure

Was not a common observation, however the authors report fracture of plate in Group A more commonly. Only in 4 patients out of 70, mini plate fracture was observed and trapezoidal plates did not show any plate fractures. Post-operative pain and infections were also associated with the patients who had plate fracture. (GRAPH 3)

8. Post-operative infection.

Most patients did not develop post-operative infection but infection due to plate fracture was seen in 1 patient.

In accordance with the above stated results, it is determined that trapezoidal plates provides better stability and has less intra operational time as compared with mini plates. Thus trapezoidal plates are a better choice for condylar fracture fixation.

DISCUSSION

Even though condylar fractures are the most common type of mandibular fractures, their treatment protocol still remains a controversy. When an informed choice of ORIF has been made according to Zide and Kents absolute and relative indications, the surgeon has a variety of plating options to choose from for his fixation. This systematic review hence chose 2 most commonly used plates i.e trapezoidal plate and mini plate for fixation of condylar fracture and compare which of these yields better outcomes. A null hypothesis was made that there will be no significant difference between performances of the two plates. The aim of this study was to compare the plates on the basis of operational time reduction of fracture segments, condylar movements, pain, screw loosening, and post-operative infection. Our systematic review concluded that trapezoidal plate provides better stability at the fracture site and has significantly less operational time.

For a surgeon, time spent on the treatment of the problem is never an issue so as to give the best treatment to the patient. But anything that reduces time and effort is much desired by anyone. On this aspect the time taken to manipulate and fix trapezoidal plate at the fracture site was significantly more as compared to 2 mini plates. Recently Transmassetric anterior parotid approach has shown to have less facial nerve injuries, fistulas and post-operative infections. The availability of a clear field is what bring adequate reduction and fixation of the segments but it is difficult to fix mini plate at the proximal segment of condyle^[1]. The transmassetric Anterior parotid approach helps in fixing that issue as well. Moreover, more the number of plates and screws, more is the time taken for fixation. Trapezoidal plate gives 3 dimensional stability to the fracture site, it is easy to manipulate and fix. The mean time for fixation for trapezoidal plate was around 6 mins but for 2 mini plates it turned out to be 15 mins. Therefore, trapezoidal plate saves time and soft tissue retraction is for lesser time there by decreasing the chances of post-operative complications such as edema and facial nerve paralysis.

Fracture reduction helps in anatomic as well as functional restoration for the patient. Adequate reduction and fixation is required to bring correct occlusion to the patient. In both the groups there was no significant difference in reduction of fracture which was assessed via radiograph post operatively. Post-operative occlusion is of the most important aspect for management of sub condylar fracture. This was checked by maximum intercuspation on occlusion. Literature suggests that obtaining a satisfactory post-operative occlusion ranges from 72 to 100 percent, and our results were in accordance with them regardless of the type of plate used in fracture reduction.

The range of mandibular movements are determined by bilateral synchronized movements of the condyle. In all the 70 patients who underwent ORIF for treatment of condylar fracture showed adequate lateral excursion, protrusive movement. Irrespective of the plate type a mean value of 15 mm of maximum mouth opening was observed using a ruler post operatively. The mouth opening significantly increased in further follow-ups.

As reported by the authors hardware failure due to plate fracture was seen in 4 cases in group A (5.71%). The tensile strains lines are mainly responsible for the complications concerning plate fracture or screw loosening that lead to the displacement of the reduced condylar fragment with the consequent presence of a gap in the fracture line. The first plate, fixed by four screws (two on each side of the fracture), is positioned parallel to the condylar neck axis, respecting the compressive strain lines in this region. This first plate helps to obtain ‘‘intermediary stability’’, so permitting the restoration of the height of the ramus. But this same plate is not capable of resisting the biomechanical strains that occur in the condylar region during mastication, and more precisely the sagittal tension correlated to the tensile strain lines that lead to the displacement of the condylar fragment with the consequent appearance of the gap. Therefore it is necessary to position a second plate in an oblique direction along the tensile strain lines that run below and parallel to the sigmoid notch, in agreement with Champy’s concept of stable osteosynthesis functionality.

The second plate protects the first plate from damaging mechanical strains that could cause its fracture and a secondary displacement of the mandibular condylar fragment reduced^[1]. Meyer's et al. in the year 2006 suggested through his experimental study that 2 non parallel mini plates cannot bare the physiologic strain the sub condylar region leading to hardware failure^[6]. Hence, the concept of trapezoidal plate was hatched, due to the shape of the plate which has been made keeping in mind the stress, strain and bone deformation occurring at the condylar region^[6] it is easier to manipulate the plate and fix it in the line of osteosynthesis regardless of high or low condylar fracture. Therefore, plate fracture was not reported in group B, emphasizing the superior stability of trapezoidal plate.

Post-operative infections were not a very common finding in any of the cases. However 1 case out of 70 patients showed infection (1.42%) in the surgical site. The infection was treated with incision and drainage. This can be avoided with aseptic environment during surgery and regular change of dressing. This promotes better and faster healing as well. Post-operative pain was usually associated with the surgical site and was maximum during the 1st week. The pain subsided eventually during further visits. The stability of the fractured segments is inversely proportional to pain. Though there was no significant difference, but the stability provided by trapezoidal plate is better as compared to a mini plate. Therefore pain is also less in group B.

In conclusion we can suggest that both the plates perform equally in the grounds of fracture reduction, functionally stable fixation, and postoperative infection and condylar movements. But trapezoidal plates are superior in terms of stability, hardware failure and time taken for fixation. These factors are very important for successful outcome of a fracture reduction. Therefore trapezoidal plate should be preferred over 2 mini plates for the reduction of condylar segments.
