

Simulation Studies on Recovery of Acetonitrile from Aqueous Acetonitrile waste from Pharmaceutical Processes

ABSTRACT

This paper presents simulation studies on the recovery of Acetonitrile from aqueous Acetonitrile waste from pharmaceutical processes. The focus is on atmospheric distillation in two sequential columns to understand the separation feasibility of the system; the first column produces a distillate of azeotropic composition, which is mixed with a fresh stream and fed to a second column, which produces a 99.9 % pure Acetonitrile in the residue. The effect of reflux ratio, reboiler duty and the fresh stream flowrate on the purity of the product is analyzed. The study was performed using steady state simulator Aspen Plus, version 11.1. The simulation results indicate that it is possible to obtain a product of 99.9 % w/w Acetonitrile from a 1:1 feed with a recovery of ~ 60%.

Keywords: Distillation, Simulation, Acetonitrile, Aspen Plus, Sensitivity Analysis.

1. INTRODUCTION

The Aim of this research is to design a simulation flowsheet to obtain pure Acetonitrile from a spent solvent stream containing Acetonitrile in water. Acetonitrile is a colorless liquid which finds many applications as it is miscible with water, has a high dielectric constant, low viscosity and low chemical reactivity. Acetonitrile is used in the production of pharmaceuticals, perfumes, rubber products, insecticides, acrylic nail removers, and batteries. It is also employed in the extraction of fatty acids from animal and vegetable oils.

Acetonitrile is one of the important solvents primarily used in the pharmaceutical industries, due to its medium polarity and the miscibility with water. The effluents from the processes involving Acetonitrile as solvent mostly consists of a binary mixture of Acetonitrile and water; it is important and ample opportunities are available for recovering Acetonitrile from the aqueous waste streams (1). Acetonitrile can be recovered using distillation depending on the initial composition of the binary mixture. The feed composition is important because the Acetonitrile-water forms an azeotropic mixture at 83 % Acetonitrile under atmospheric conditions.

Distillation is a mass transfer operation which separates two or more components into two streams which are more concentrated in one of the components. The separation is based on the relative volatility of the components in the feed stream. The overhead product, called as the distillate can be collected as a vapor or a liquid and is rich in more volatile component(s). The residue collected from the bottom of the column consists of the less volatile or the low boiling components.

Configuration of the column, feed composition, process conditions and target purity of the desired product are major factors that affect a distillation operation. The column configuration can be specified in terms of the total theoretical stages and feed location, where as the operating parameters that influence the performance of a column include reflux ratio, boil-up ratio, condenser and reboiler heat duty.

It is important to understand the effect of these variables on the desired product purity and the throughput from the system. Simulation studies provide relevant and significant results corresponding to the variation

51 of any operation/process with respect to factors effecting them. It is safe, inexpensive and consumes less
52 time than experimental effort in understanding the system under study.

53 2. LITERATURE REVIEW

54 There are a few papers published related to the simulation studies on distillation of binary mixtures (2–5).
55 Lone and Rather (2) have performed simulation studies of a distillation column for the separation of 1:1
56 Methanol-water system. The objective of the study was to find optimum feed stage location, total number
57 of stages and the optimum reflux ratio to obtain 99.5% pure methanol in distillate and 99.5% pure water in
58 the residue. Aspen plus simulation software was used. Lone and Akhlaq (3) have developed a rigorous
59 model for the simulation of the steady-state behavior of the distillation column, solving the model using
60 MATLAB, they have presented the effect of feed condition and the feed composition on the steady state
61 behavior of a distillation column for separation of Methanol-MTBE-Isobutylene. With Isopropyl Alcohol-
62 Water system as case study, Yadav et al (4) have performed steady state and dynamic simulations using
63 Aspen Plus, to depict the behavior of the system. They have presented the concept of degrees of
64 freedom, variables effect and systematic working procedure of Aspen Plus and simulated the effect on
65 mole fraction of liquid phase, vapor phase with changes in temperature, pressure, activity coefficients,
66 respectively. Shorey (5) have presented a comparative study on simulation of distillation column for
67 methanol-water system using DWSIM and ASPEN Plus. The author focused on providing the insights on
68 the obstacles faced in simulations carried out using an open source software.

69
70 Separation of Acetonitrile-Water mixtures, is often performed using membrane separation techniques(6–
71 9), extractive and azeotropic distillation(10–12) and pressure swing distillation(13).While membrane
72 separation can be an effective method for separating Acetonitrile-Water mixtures, there are several
73 potential disadvantages in terms of membrane selectivity, cost, degradation, fouling and energy
74 requirements. The azeotropic/extractive distillation involves entrainer/solvent, which causes issues with
75 selectivity, limited separation ability, higher energy consumption and recovery of the entrainer/solvent.
76 Pressure swing distillation offers another promising method for the separation of Acetonitrile-Water
77 mixtures, however it is marred by the high energy consumption, equipment complexity, scalability and
78 process control challenges. Also the rapid pressure changes may create safety concerns.

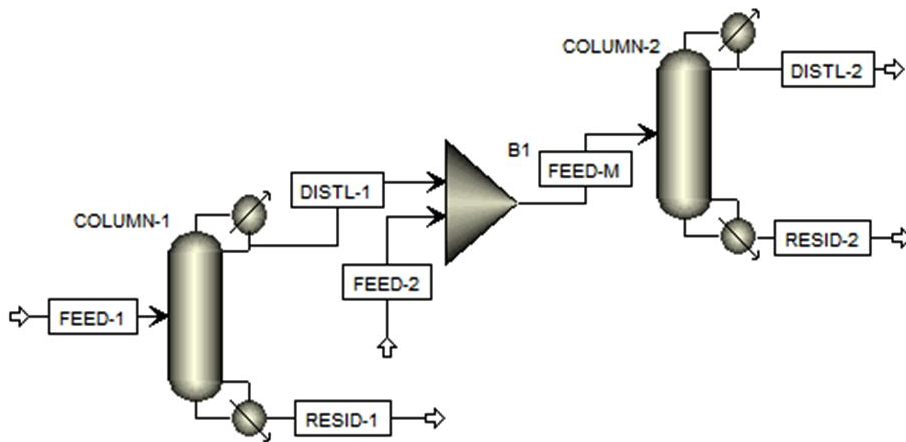

79 3. MATERIALS AND METHODS

80
81 In the present paper, a flowsheet/separation methodology is proposed that uses 2 columns to achieve
82 99.9 % pure Acetonitrile. The first column produces a stream with azeotropic composition and a fresh
83 stream of Acetonitrile is added to this stream and fed to the second column to obtain 99.9 % pure
84 Acetonitrile. A feed of 50 % w/w of Acetonitrile and 50 % w/w water is considered for separation and
85 simulation studies were performed to understand the separation feasibility of the system and the effect of
86 reflux ratio, reboiler duty and the fresh stream flowrate on the purity of the product. Steady state simulator
87 Aspen Plus, version 11.1 was used for performing the simulations. It is a commercially available software
88 for the simulations of systems from chemicals, polymers and life sciences industries.

89 The steps followed were:

- 90 i) Defined components and selected NRTL thermodynamic model for estimation of physical
91 properties and binary interactions.
- 92 ii) Estimated the properties of the binary system; studied T-xy plot and the variation of the
93 azeotropic composition at varying pressures to understand the optimum vacuum for the
94 distillation.
- 95 iii) Created flowsheet with two sequential columns with RADFRAC model.
- 96 iv) Preliminary simulations were performed.
- 97 v) Sensitivity analysis was done.

98
99 The flow sheet is shown in **Error! Reference source not found.** As the Acetonitrile-water system forms
100 an azeotrope at 83 % w/w of Acetonitrile a single distillation column would not be sufficient to get a purity
101 of > 83 % w/w of Acetonitrile. Thus, the distillate from the first column was sent to mixer where a fresh
102 stream of Acetonitrile was added, and then this mixed stream was fed to a second column. The second
103 column was optimized to yield a distillate containing > 99.5 % w/w of Acetonitrile.

110 **3.1. Column Configuration**

111
112 A series of two columns was considered for the present case study. The first column, COLUMN-1
113 consists of 10 number of stages and the second column, COLUMN-2 has 15 number of stages. Both the
114 columns are connected to total condensers. The distillate from COLUMN-1 was passed to a mixer, B1
115 where it is enriched with fresh 99.9 % w/w pure Acetonitrile and fed to a second column, COLUMN-2, to
116 obtain a residue of ~ 99.9 % w/w from the COLUMN-2. The configuration of both the columns is given in
117 Table 1 and the feed specifications are given in
118 Table 2.

4. RESULTS AND DISCUSSION

The **Error! Reference source not found.** and **Error! Reference source not found.** respectively shows the T-xy and y-x Diagram for the Acetonitrile-water Binary System. Under atmospheric conditions, Acetonitrile-water forms a minimum boiling azeotrope at 83 % w/w of Acetonitrile. The variation of azeotropic composition under vacuum was then evaluated and is shown in Table 3. The data in Table 3 indicates the possibility of obtaining 99 % w/w purity of Acetonitrile in a single distillation set-up under high vacuum of 750 mmHg. However, operating feasibility and the economics of the process has to be considered in detail. The present study is focused on the atmospheric distillation in 2 sequential columns.

Atmospheric distillation of feeds of Acetonitrile and water comprising less than 83 % w/w of Acetonitrile would produce a distillate of maximum purity equal to the azeotropic composition. For this reason, in the present study two columns were considered in series. With an aim of obtaining Acetonitrile greater than 98 % w/w purity, fresh stream of Acetonitrile (99.5 % w/w) was mixed with the distillate obtained from Column-1 and fed to the Column-2. This addition of fresh stream of Acetonitrile, changes the feed composition for the Column-2. The distillation in the second column produces a distillate closer to azeotropic composition and a residue of purer Acetonitrile. The stream results corresponding to the base case simulation are given in

155 Table 4. The recovery of 99.9 % w/w Acetonitrile is 45.8 %. The base column configuration and the
 156 operating parameters can be optimized for the desired purity of Acetonitrile.

160
 161 The temperature and concentration profiles for both the columns are shown in Figure 4. Temperature
 162 ProfileFigure 4Error! Reference source not found., Figure 5 and Figure 6. Column-1 operates at higher
 163 temperatures, when compared to the Column-2 as the water content is higher yielding a higher boiling
 164 point for the mixture at every stage. The temperature in both the columns decreases from the reboiler to
 165 the first stage. The reboiler of Column-1 is at 353.7 K, whereas the reboiler of Column-2 attains 350 K.

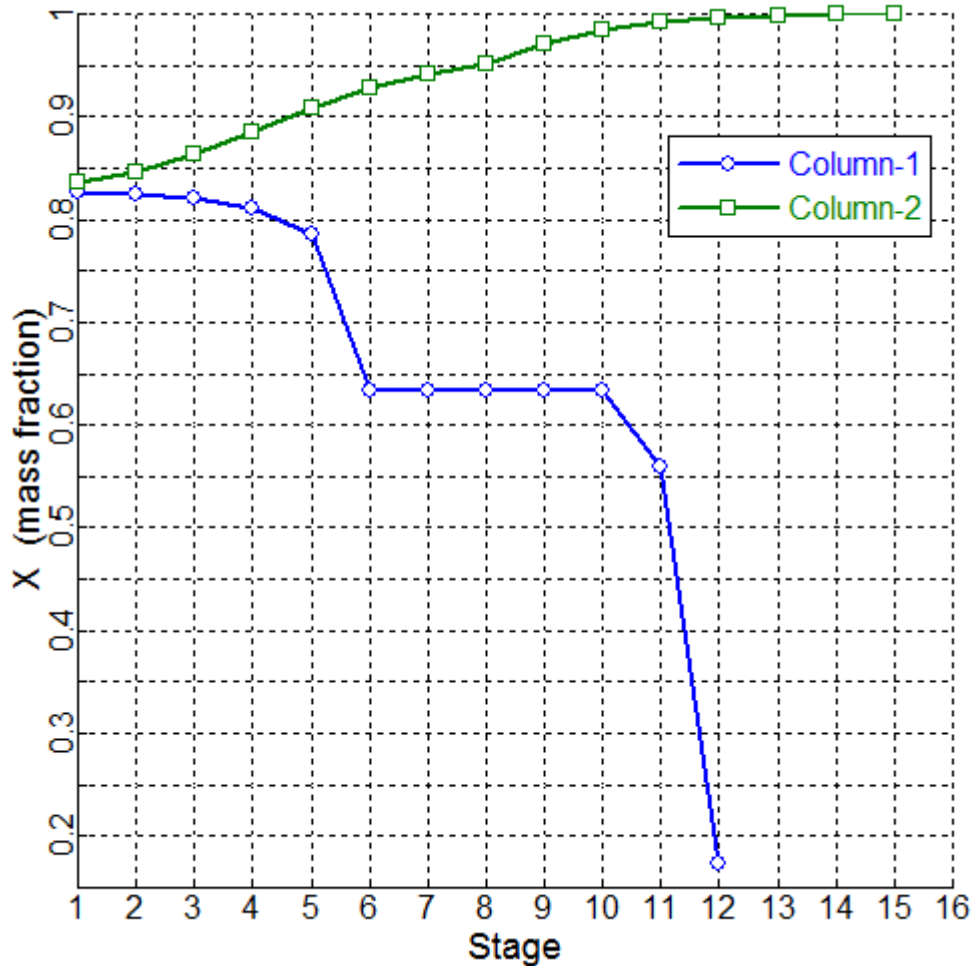

166
167 Figure 4. Temperature Profile

168
169 Figure 5. Vapor Composition Profile

170
171 The Vapor composition of Acetonitrile in both the columns is shown in Figure 5. Interestingly, in the
172 Column-2 the vapor composition of Acetonitrile increases towards the bottom of the column, whereas it
173 increases towards condenser in the Column-1. This is because in the Column-1 the separation is
174 between the water and the azeotropic mixture of Acetonitrile and water, while in the second column
175 separation is between the azeotropic mixture and Acetonitrile. The azeotrope formed boils at ~ 350K. The
176 boiling point of Acetonitrile is 355 K and that of water is 373 K. as shown in **Error! Reference source not
177 found.**, the maximum composition of the Acetonitrile obtained from the Column-1 is 83.4 % w/w. Figure 6
178 shows the variation of composition of Acetonitrile in the liquid in both the columns. It follows a trend
179 similar to the vapor composition profiles; highest mass fraction of the Acetonitrile is seen in the bottom
180 stage of Column-2. Acetonitrile of desired composition is obtained as residue from Column-2.

181
182 Figure 6. Liquid Composition Profile for Acetonitrile

183
184 **4.1. Sensitivity Analysis**

185
186 Aspen plus software provides a model analysis tool that facilitates the optimization of the model with
187 respect to the selected variables.

188
189 For the COLUMN-1, sensitivity analysis was performed, to optimize the number stages, the location of
190 feed stage and Reflux ratio to maximize the distillate rate.

191
192 The variation of distillate rate with total number of stages is shown in Figure 7. The figure shows an
193 increase in distillate rate with an increase in number of stages up to 8 total stages, for a fixed reflux ratio
194 of 1.5. For further increase in number of stages, the distillate rate was observed to be constant at 5.95
195 kg/hr. Similar trend was found for the variation of the distillate rate with feed stage location; maximum
196 distillate rate is obtained when the feed is provided on stage 6. This plot is shown in Figure 8. The effect of
197 increase in reflux ratio on the distillate rate is shown in Figure 9. The distillate rate was observed to
198 decrease with an increase in the reflux ratio. So a reflux ratio of 1 is chosen as optimum for further
199 simulations.

211

212 The mass fraction of Acetonitrile in the residue of Column-2 was chosen as the objective variable and
 213 sensitivity was analyzed for the following parameters.

214

215 i) Reflux ratio

216 ii) Reboiler Duty, and

217 iii) The amount of fresh Acetonitrile added to mixer to change the feed composition for COLUMN-2.

218

219 Figure 10 shows variation of mass fraction of Acetonitrile with reflux ratio. For this column, the reflux ratio
 220 up to 2.5 gives > 99.9% pure acetonitrile, further increase in reflux ratio results in the decrease in the
 221 purity of the acetonitrile recovered. The reflux ratio of 1.5 as in the base case simulation is chosen as
 222 optimum.

Figure 10. Variation of Mass Fraction of Acetonitrile with Reflux Ratio in Column-2

The increase in the reboiler heat load for the Column-2, as shown in Figure 11, has major effect on the purity of Acetonitrile obtained from the column. A ten fold increase in the reboiler duty enhances the mass fraction from 0.913 to 1. Nevertheless, it is important to study energy efficiency of the column to decide the reboiler heat load. 3960 kCal/hr is chosen as the optimum reboiler duty.

 246

Figure 11. Variation of Mass Fraction of Acetonitrile with Reboiler Duty for Column-2

The effect of total number of stages in Column-2 is shown in Figure 12. Increased number of stages increases the purity of residue. At least 10 stages are required to obtain a 99.9 % Acetonitrile. The increase in the fresh feed added to the mixer to change the composition of the feed to Column-2 significantly effects the purity of Acetonitrile obtained. The distillate obtained from the Column-1 is mixed with a stream of 99.5 % w/w Acetonitrile in the Mixer B1 to alter the feed composition to Column-2. Whence, the rate at which the fresh feed is added to mixer has substantial effect on the residue rate as well as composition from the Column-2. This effect of varying feed rate of fresh feed on the residue composition is shown in Figure 13. The residue rate increases and the purity decreases with the increase in feed flow rate. The flow rate then needs to be optimized based on the economics in terms of the yield of the Acetonitrile from the column. The variation of residue rate from Column-2 with the fresh stream flow rate is shown in Figure 14. The residue rate also depends on the reboiler duty.

5. RECOVERY OF ACETONITRILE

The recovery of Acetonitrile is evaluated from the following equation.

$$\text{Percentage Recovery} = \frac{\text{Amount of Acetonitrile Recovered}}{\text{Amount of Acetonitrile fed to the system}} \times 100 \quad (1)$$

Amount of Acetonitrile recovered will be the quantity of Acetonitrile obtained in the bottoms stream from the COLUMN-2. The denominator term must include Acetonitrile in feed to both the columns.

For the base case simulation, the percentage recovery of Acetonitrile was evaluated to be 45.8 %. For the optimized system, the recovery of 99.9% pure Acetonitrile from the system increased to 60.4 %.

6. CONCLUSION

The case study envisaged in the present paper, to recover 99.9 % w/w Acetonitrile from 1:1 aqueous Acetonitrile stream by atmospheric distillation indicates the possibility of recovery using 2 sequential columns. Obtaining azeotropic mixture of acetonitrile-Water from a 50 % w/w mixture is considerably easy and requires a smaller number of stages and less reflux conditions. The second column was optimized for reflux ratio, reboiler duty and amount of fresh feed of Acetonitrile given to the mixer before Column-2 to change the composition of the feed to Column-2. The purity of Acetonitrile obtained from Column-2 was found to be 99.9 % w/w. The recovery of acetonitrile from the proposed optimized set-up increased to 60.4 % from the base case considered for simulation. Further optimization in terms of process economics needs to be done.
