

Editor's Comment:

The author has addressed the comments of the peer reviewers. I would like to add a few more queries. In case 2, were there similar ulcers in the skin other than the manifestations caused by allergic reaction? Was an immunofluorescence test done in case 2. If so please mention the findings. And also that immunofluorescence tests is associated with false negative results in chronic conditions as mentioned by you in the manuscript, could it be considered a gold standard? Or better than a biopsy? Please clarify on this. On the whole the manuscript could go for publication after taking these facts into consideration.
