Original Research Article

Floristic Assessment of Natural Regeneration, 8 years after Post-Remediation by Enhanced Natural Attenuation (p - RENA) of Hydrocarbon Impacted Land: A Window for Selection of Native Macrophyte with Remediation Potential.

ABSTRACT

Aim: The study was aimed at revealing the composition and demographic status of forest regeneration in a hydrocarbon impacted site after 8 years of post remediation by enhanced natural attenuation.

Study design: A stratified systematic transect method was used to assess the regeneration status.

Place and Duration of Study: Field sampling: in parts of Edovna vegetation landscape in Emohua Local Council area of Rivers State, Niger Delta, Nigeria and site remediation activity carried out for 10 weeks.

Methodology: site remediation treatment technique, Vegetation assessment, Regeneration Assessment and data analysis were carried out.

Result: A total of 115,549 seedlings and 7,825 saplings ha^{-1} of 96 recruits of 70 genera under 23 families of angiosperm were found in 800 m^2 sampled site. Among the dominant families Poaceae was the richest (24 species) in species diversity and across the phytosociological composition of recruits has recorded highest frequency (1675), abundance (621), density ha-1 (49,600), IVI (104.81), diversity richness (11.75) and evenness (5.96). Herbaceous herb (HH) recorded the highest number of recruits among the regenerating life forms (*HH>HG>Sh>HCl>HS>ShCl>T*) across phytosociological composition. The environmental adaptiveness and resilience among recruits revealed Chamaephytes and Hemi-cryptophytes across diverse herbaceous life forms as well as Mesophanerophytes, Microphaneropytes, Nanophanerophytes and Hemi-cryptophytes across shrubby life forms and a megaphanerophyte of the tree life form recorded. Across the degree of percentage mode of regeneration life form herbaceous life form had 40 recruits that exhibited 12 multiplier and 4 single mode of regeneration respectively. In shrubby life form four recruits exhibited 2 multiplier and 13 recruits exhibiting 2 single mode of regeneration.

Conclusion: The demographic status of regeneration revealed a greater seedling density than sapling density thus implying a successful and new regeneration which through protection of natural regeneration can return back to it complete forest cover again.

Key Words: *Demography, life form, phytosociology, recruits, regeneration, **v**egetation.*

1. INTRODUCTION

Oil pollution whether acute or chronic has simultaneous and / or instantaneous deleterious effect on environmental landscape. The impact of hydrocarbon pollution on environmental media involving soil, air, and water and associated ecosystem of communities have been documented in several studies [1, 2, 3, 4, 5, 6, 7,8,9]. Therefore the incidence of oil spill constituting diverse environmental damage may not be overemphasized. However, different parts of the Niger Delta region have in the past experienced and currently faces serious ecosystem depletion from the activities of hydrocarbon industries. Thus affecting the environment in the operational areas, right of ways (ROW) and third party areas including the vegetation landscape of Umuobizu around the Shell Petroleum Development Company (SPDC) marginal oil field manifold in Emuoha study area. The Emuoha study area is one of the agrarian communities among the upland localities of Rivers State. The area is known for its diverse unique, natural and socio-economically important biodiversity. Among such biodiversity are the rich vegetation systems of distinct patches of low land primary and secondary tropical rainforest with adjoining fresh water forest locally known as "Ugologo, Mininknu, Miniowhna, (i.e. Wetland forests); low land bush fallowed vegetation known as Ejohia (evil forest); low land agronomic vegetation land scape involving various farm lands with local names as: Okologba, Alinkpu, Uzookohia, Oriogbo, ovuzor, Owhela, Uzoomuobizu, and adjoining ROW low land vegetation land scape locally known as Nzuruptata and **Edovna forest (**p-RENA project site) at Umuobizu.

The threat posed by the impact of hydrocarbon on the Edovna forest and its adjoining vegetation cover can be adequately addressed via concerted effort. This requires understanding of the diversity and natural dynamics of plant species, (causes, mechanisms and factors) that drive the process of regeneration of plant species as well as population change and replacement over time to maintain the remaining patches of forest vegetation [10, 11]. Understanding and managing the disturbances of landscape under past natural and semi-natural regeneration condition is one of the bases for conservation of biodiversity in vegetation landscapes [12]. Furthermore, the crucial role of natural regeneration in the sustainable management of forest and woodland resources has been demonstrated [13].

The occurrence of oil spill and subsequently the physical clean-up (as containment, recovery and surface scarification) by operating companies, usually render the lands bare, without adequate reforestation to restore the environment to its natural or near-natural status. Recruitment, growth, and survival are influenced by a range of microclimatic and edaphic factors, which vary among different tropical forest vegetation formations [14]. However, 8 years after the spill in 2005, without any form of replanting and recuperation at Umuobizu, the impacted site after 8 years of p-RENA in 2013 has started recuperating by natural regeneration of recruits in diverse life forms. Regeneration of any species holds a vantage point for the perpetuation of forests vegetation, and the existence and valuation of recruits, in terms of seedlings, sapling, and coppices. Parameters of seedling stands are crucial components of population dynamics [15]. As floristic and structural composition changes from one community to another there are also changes in the competitive abilities of seedlings that depend on shifting opportunities for regeneration [16]. Earlier studies of tropical tree regeneration have focused mainly on seedlings, which are usually more abundant than other demographic status [17; 18]. Research has shown that plant species in their diverse capabilities on a post-remediated hydrocarbon polluted site can re-establish through various mode of regeneration status such as coppicing, seedling, rhizome and sapling with few of resilient species exhibiting multiplier mode of regeneration [15, 19].

Although there have been reports of investigations on natural regeneration of polluted and post-remediated site, but there is limited investigation of such in Emuoha area of Rivers State. Thus it has become exigent to evaluate the demographic ability of native plant species natural regeneration status at Umuobizu marginal oil field for remediation potential in Emuoha Council Area of Rivers State. It is one of the best and easy ways to find a plant species suitable for phytoremediation. Several plant species by natural regeneration have demonstrated resilience and remediation potentials in contaminated or polluted sites [20, 21, 22, 23]. Yet there is paucity on plant species natural regeneration in parts of Niger Delta hydrocarbon impacted sites particularly in remediated sites. This study was therefore aimed at evaluating the remediation potential of some hydrocarbon tolerant macrophytes, (HTM) with the objective of understanding their fate of natural recruits based on the mode of regeneration across their demographic status in crude oil hydrocarbon post-remediated soil habitat in parts of Emuoha Council Area of Rivers State, Nigeria.

2. MATERIALS AND METHODS

2.1. Study area, location and site:

The study area was Emohua Local Council, situated between Lat. 04^{o}25'4"N to 05^{o}25'20"N and Long.06^{o}30'27"E to 07^o 31'36"E (Fig 1) is among the 23 Local Government Areas in Rivers State, South-South Nigeria. It is one of the oil exploration areas in the Niger Delta region of Nigeria. The area is generally low-lying with diverse forest vegetation land scape characterized by disturbances of oil exploration activities. It is predominantly an agrarian community of farmers, hunters and fishermen fully exploiting the rich biodiversity of the area. The edaphic condition of the area is a sandy-loam soil texture rich in nutrients composition of organic and inorganic components. The successive vegetation of the area is characterized by prevalent species of diverse life forms. The study area is characterized by two seasons, (Rainy and Dry seasons) with an annual rainfall between 2400 - 4000mm and maximum temperature range of 28°C for its hottest month and 26°C as lowest temperature in its coldest month [24]; diurnal variation seldom exceeded 15°C. The study area is comprised of over 31 communities among major towns and villages including: Ogbakiri, Emuoha, Odoegu, Elele-Alimini, Rumuekpe, Akpabu, Egbeda, Obele-Ibaa, Omudioga, Ubimini, Egamini and the study location **- Ibaa**.

The study location – Ibaa with its' situate between Lat. 4°50'0"N – 5°0'0"N and Long. 6°40'0"E – 5°0'0"E (Fig. 2) is a secondary vegetation low land habitat lying in the rainforest belt of Rivers State within the equatorial climate region characterized by maximum rainfall, relative humidity and maximum temperature associated with the study area. The study site – Umuobizo and its environ geo-referenced to Lat.4°55'0"N to 4°58'0"N and Long. 6°48'0"E to 6°50'0"E (Fig. 3) is an agrarian community with its adjoining ROW low land vegetation land scape locally known as Edovna forest rich in forestry resources for their traditional ethnobotanical and agrarian utilization.

The Edovna forest vegetation system is associated with network of crude oil pipeline Right of Ways (ROWs) linking the SPDC marginal oilfield manifold. The Edovna forest ecosystem was often designated as one the landscape for agronomic activities before the discovery of oil in the area, thus was given up as one of the SPDC marginal oil field manifold. The edaphic and topographic status revealed a table land characterized by sandy loam soil.

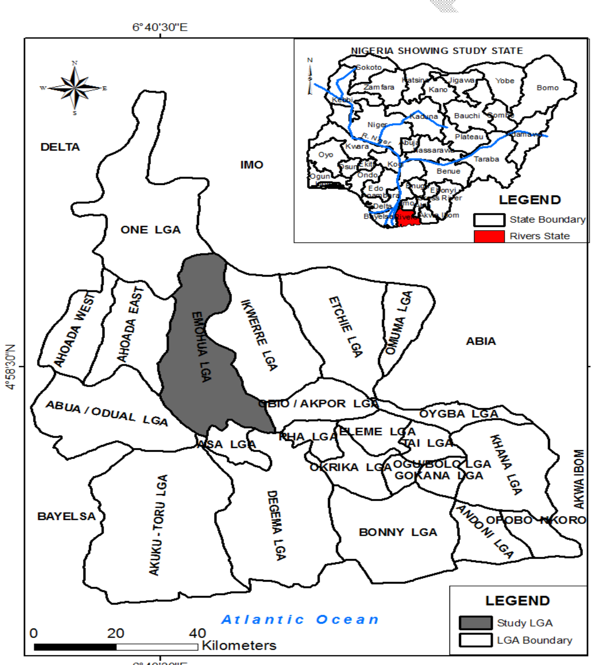

Fig. 1: Rivers State showing study area- Emohua

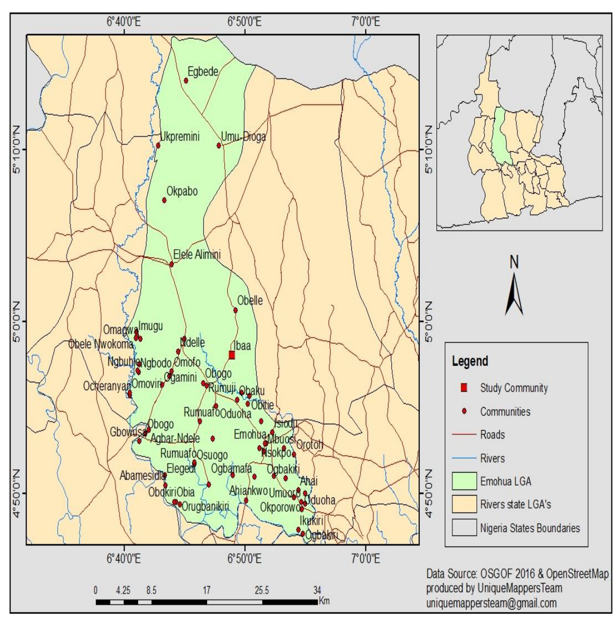

Fig. 2.: Emohua study area showing study location - Ibaa

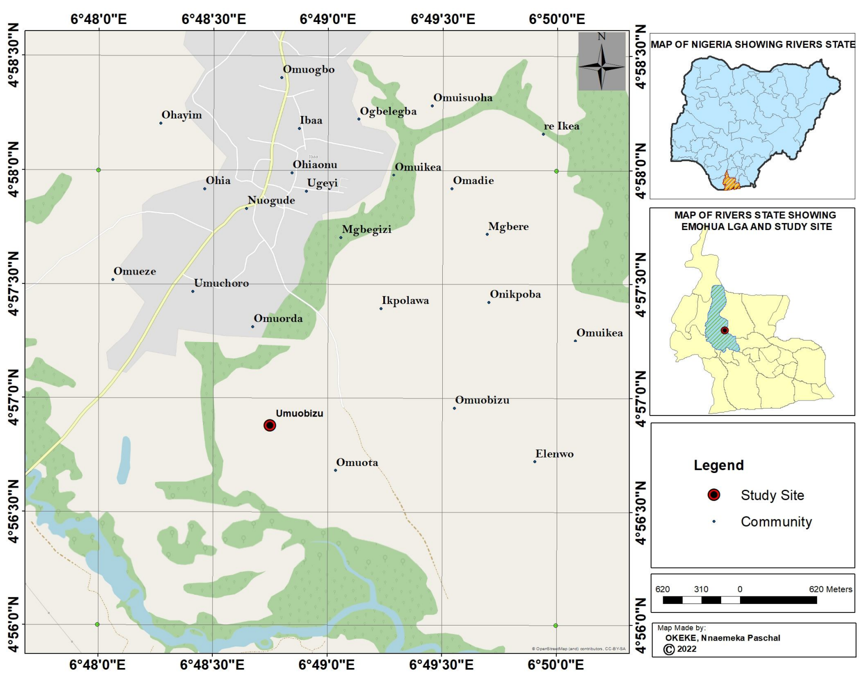

Fig. 3: Ibaa town showing study site- Umuobizu

Originally it was a climax vegetation of various strata based on Key Informant Interview (KII) [25] however was observed to be under retrogressive ecological succession. This was due to anthropogenic influence of hydrocarbon exploration, farming activities far and near residential areas as well as encroachment to ROWs by the local inhabitants coupled with the impact of post-oil spill in 2005 thereby leaving the study location with some form of irregular vegetation features with heterogeneity; characterized by prevalent species of herbs, shrubs, climbers, liana and under the prevailing local condition dominated by suspected hydrocarbon tolerant families including; Poaceae, Euphorbiaceae, Rubiaceae, Tiliaceae, Cyperaceae, Commelinaceae, Asteraceae, Convolvulaceae, Malvaceae, Onagraceae, Fabaceae, Sterculiaceae, and Acanthaceae plant families. However, the vegetation landscape of the area can still be described as rainforest vegetation corroborating the views of Edwin-Wosu and Edu, [19].

2.2. Study site remediation treatment technique:

An integrated approach of Focused Group Discussion (FGD) and Key Informant Interview (KII) at the period of reconnaissance survey and enumeration was carried out. With the site still bared of vegetation 8 years after the oil spill incident in 2005, RENA remediation technique was adapted. This was applied on the crude oil hydrocarbon impacted soil in 2013 following containment and recovery of oil in the pollution incident of 2005 around the SPDC manifold at Umuobizu marginal oil field, Ibaa. It involved initial tilling using shovels after four weeks at the end of recovery. The second tilling after 14 days was to break and homogenize lumps of soil in the crude oil impacted site and allowed to stand for another 14 days. This was followed with soil ridges of about 1x1foot windrow been constructed and allowed to stand for about another 14 days. At the 14 day elapse of the windrow ridges, shovels and rakes were used to break down ridges for effective exposure to local environmental condition. The breaking and gathering of windrow ridges were to enhance porosity, soil aeration and moisture content that would promote biodegradation activities of resident microorganisms, enhance natural regeneration and recruitment of plant species. The exposed site was under monitoring and evaluation for 8 years after RENA, upon which second enumeration in 2021 was carried out to ascertain the degree and demographic status of natural recruit regeneration.

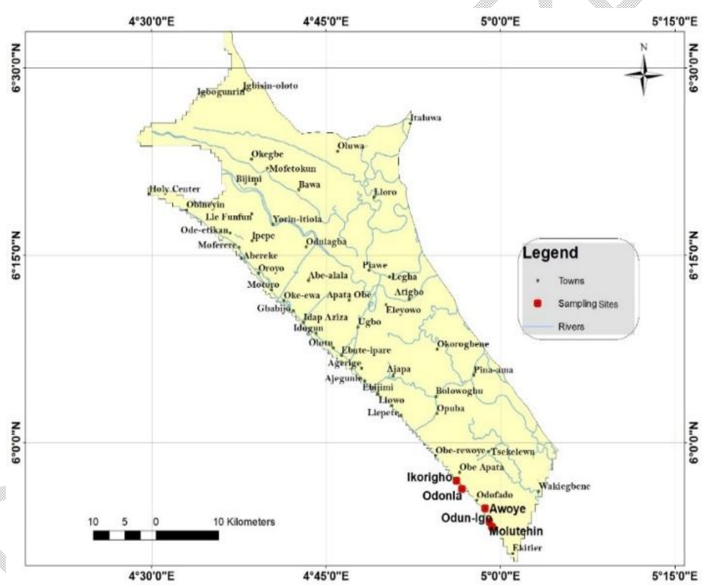

Fig.4: Ilaje –study location indicating sampled sites

2.3. Vegetation assessment

This study adopted an integrated approach involving: Stratified randomized designed, sub-sampled units (10 x 20m) of sampled plot (40 x 20 meters) in a Systematic transect design outlay [26]; Geospatial tools (Geographical Positioning System (GPS); Remote Sensing (RS); Geographic Information System (GIS) (BHnav 300 model ESRI'S ARCMAP version 10.4); Floristic assessment by Identification / Authentication [27-31, 32,33, 34-38,39,40].

2.4. Regeneration Assessment

The regeneration assessment [41] was based on trend condition of the following demographic indices: "**Good**" when seedling density > sapling/coppicing density > adult tree density.

"**Fair**" when seedling density > sapling/coppicing density = adult density.

"**Poor**", when the species survived in only the sapling/coppicing stage but not in the seedling stage.

"None", for species with no sapling/coppicing or seedling stages but present as adult trees.

"**New**" when adults of a species were absent but sapling / coppicing and/or seedling stage(s) were present.

2.5. Data analyses

Data was analysed for percentage Frequency [42]; Abundance [43]; Density Chikkahuchaiah *et al*. [44]; Relative frequency, Relative abundance, Relative density [45]; Coefficient of frequency Pryor scale semi-quantitative (+ ---- >) representation, [46]; Importance Value Index [47]; Species diversity richness: (H') = $- \sum \rho i \ I\eta \ \rho i$ [48]; Species evenness or Equitability Index: $E = H'/ Log.S$ [49]; Life form spectrum *I* classification [50]; Distribution patterns: Ratio of Abundance: Frequency (A/F): Regular (< 0.03), Random (0.03 - 0.05) and Contiguous (> 0.05) [51].

3. RESULTS

i. Floristic classification, structure and composition

The Edovna forest following the p-RENA process was under the influence of progressive secondary succession impact. Such succession resulted to a classified flora trend of lowland secondary vegetation with mosaic nature, heterogeneous continuum in spatial and closed horizontal assemblage of structural arrangement. By the floristic composition there was changes and variation among various life forms of 96 representative species of 70 genera under 23 families of angiosperm (Table 1). Diverse dominance of families (Poaceae, Cyperaceae, Fabaceae Commelinaceae, Malvaceae, Tiliaceae, Asteraceae, Rubiaceae, Euphorbiaceae, Sterculiaceae, Passifloraceae and Amaranthaceae) were recorded among regenerating recruits. Eight families were very abundant with the highest diversity species richness. Poaceae (30.38%) had 24 species, Cyperaceae (11.39%) 9 species, Fabaceae (16.46%) 13 species, Asteraceae (6.33%) 5 species, Rubiaceae and Euphorbiaceae (7.60%) 6 species respectively, and Sterculiaceae and Amaranthaceae (5.06%) 4 species respectively. Four families (Commelinaceae, Malvaceae, Tiliaceae and Passifloraceae) with respective percentage and three species each were in abundance (Table 1).

The family phytosociological composition indicated Poaceae with the highest composition of frequency (1675 = 27.96%), abundance (621 = 36.67%), density (49,600 = 40.18%) ha^{-1}, IVI (104.81 = 34.95%), species diversity richness (11.75) and evenness (5.96) values recorded across phytosociological indices (Table 1). Verbanaceae, Euphorbiaceae, and Vitaceae respectively recorded least frequency (25 = 0.42%). Least composition across abundance (5 = 0.30%), density (125 = 0.10%) ha^{-1} and IVI (0.82 = 0.27%) was recorded by Vitaceae. Arecaceae recorded least density (125 = 0.10%) while Aizoaceae had the least species diversity richness (0.05) and evenness (0.03).

ii. Phytosociology of habit based life form recruits.

The life form based on habit of regenerating recruit recorded variation in the phytosociological indices in their relative percentages among the herbaceous (78), shrubby (15), tree (1) and shrub climber (2) life forms of the representative species (Table 2). Among the herbaceous grass (HG) recruits result indicated 10 species with the highest frequency (100%) of occurrence and six individual recruits with least frequency (25%) class. The herbaceous sedge (HS) recorded three species (*C. esculentus, C. haspan,* and *C. iria*) with highest (100%) frequency class and three species (*M. longibrecteatus, K. erecta* and *M. alternifolius*) of least (25%) frequency among the regenerating recruits. The herbaceous herb (HH) life form has recorded 9 species with highest frequency (100%) of occurrence and seven species of least (25%) frequency among the regenerating recruits. The herbaceous climbers (HCl) of highest frequency (100%) were two recruits (C. *mucunoides* and *D. sermentosa*) and four recruits of least (25%) frequency occurrence. Generally in all bounding coordinates the frequency of herbaceous recruits has recorded a varying trend of occurrence in the order of *HH > HG > HCl > HS* by percentage ratio of 43.35: 30.01: 13.79: 9.85 respectively. The shrubby life form (Sh) had one species (*T. rhomboidea*) with highest frequency (100%) and four recruits with least frequency (25%) of occurrence while the shrubby climbers (ShCl) had two recruits (*C. splendense* and *P. muellerianus*) with least frequency (25%) of occurrence respectively and a varying trend order of *Sh > ShCl* by ratio of 93.94: 6.06. A tree life form (*E. guineensis*) of 50% frequency of occurrence was recorded. On the whole the herbaceous recruits recorded a greater frequency (5,075), than shrubby recruit (775), and shrubby climber and tree recruit (50) respectively.

Two recruits (*E. ciliaris* and *C. dactylon*) recorded highest abundance (62.50 = 3.69%) and *B. lata* least abundance (3.00 = 0.18%) among the HG life form. *Cyperus iria* with highest abundance (50 = 2.95%) and *M. alternifolius* least abundance (15 = 0.89%) among HS life form recruits was recorded. The HH recruits recorded highest abundance (50 = 2.95%) with *S. leptocarpa* and least abundance (3 = 0.18%) with *Eclipta alba*. The HCl recruit showed highest abundance (39 = 2.30%) with *P. foetida* and least abundance (3.00 = 0.18%) with *Hibiscus* *suratensis*. Generally, the herbaceous recruits have recorded variation in abundance in the order *HG>HH>HS>HCl* by ratio of 40.76: 34.36: 14.49: 10.39. A shrubby recruit (*A. indica*) with highest abundance (17.50 = 1.03 %), *M. arboensis* least abundance (3.00 = 0.18 %) with shrubby climber (*C. splendense*) in highest abundance (6 = 0.35%) and *P. muellerianus* with least abundance (5 = 0.30%) were respectively noted with a varying order of *Sh > ShCl* by ratio of 93.38: 6.62. A tree life form (*E. guineensis*) with 2.50 abundance was recorded. An overall abundance (1523.43) of herbaceous, shrubby (155.24), tree (2.50) and shrubby climber (11) recruits were recorded.

The highest density (6,250ha^{-1} = 5.07%) was recorded in two regenerating recruits (*E. ciliaris* and *C. dactylon*) and *B. lata* in least density (75ha^{-1} = 0.06%) among herbaceous grass (HG) life form. *Cyperus iria* in high density (5000ha^{-1} = 4.05%) and *M. alternifolius* in least density (375ha^{-1} = 0.30%) among HS life forms, while *S. leptocarpa* in high density (5000ha^{-1} = 4.05%) and *Eclipta alba* in least density (75ha^{-1} = 0.06%) was noted among HH recruits. Herbaceous climber (HCl) of highest density (2500ha^{-1} = 2.03%) and least density (75ha^{-1} = 0.06%) was recorded by *Calopogonium mucunoides* and *Hibiscus suratensis* recruits respectively. Generally, the herbaceous recruits showed variation in the density ha^{-1} of individuals in the orders of *HG> HH>HS>HCl* by percentage density ratio of 43.27: 34.55: 12.89: 9.29. *Triumfetta rhomboidea* was noted for highest density (1125ha^{-1} = 0.91%) with *M. arboensis* recording least density (75ha^{-1} = 0.06%) among the shrubby recruits, while shrubby climber (*C. splendense*) in highest density (150ha^{-1} = 0.12%) and *P. muellerianus* with least abundance (125ha^{-1} = 0.10%) were recorded with a varying order of *Sh > ShCl* by ratio of 96.81: 3.19. A tree life form (*E. guineensis*) with 125 density ha^{-1} was recorded. On the whole an herbaceous recruit density of 114,625ha^{-1} and shrubby recruit (8,625ha^{-1}).

The importance value index (IVI) recorded the following across the life forms. *E. ciliaris* and *C. dactylon* highest IVI (10.43%) and least IVI (1.21%) in three recruits (*I. rogosum*, *B. deflexa* and *P. maximum*) members of HG; HS highest IVI (5.17%) in *F. littoralis* and least IVI (1.61%) in *M. alternifolius* respectively; the HH recruits highest IVI (8.67%) in *S. leptocarpa* and least (1.05%) in *C. benghalensis, V. cineria and M. melissifolia*; HCl highest (5.18%) IVI in *C. mucuniodes* and least (0.66%) in *Hibiscus suratensis*. Generally an herbaceous IVI order of *HG> HH>HS> HCl* by relative percentage ratio of 39.06: 37.16: 12.73: 11.05 was recorded. The shrubby recruits recorded a highest IVI (2.85%) in *D. tortusum, T. cordifolia* and least (0.66%) in *M. arboensis,* while shrubby climber (*C. splendense*) in highest IVI (0.89%) and *P. muellerianus* with least abundance (0.82%) were recorded with a varying order of *Sh > ShCl* by ratio of 94.72:5.28. A tree life form (*E. guineensis*) with 1.08% IVI was recorded. On the whole an herbaceous recruit IVI of 268.34 and shrubby recruit IVI (32.37%) was recorded.

The Shannon-Weinner species diversity richness and evenness noted *E. ciliaris* and *C. dactylon* for highest richness (1.88); evenness (0.95) and least richness (0.01); evenness (0.01) for *S. megaphylla* and *S. pumila* respectively among HG recruits. *Cyperus iria* with highest richness (1.33); evenness (0.67) and least richness (0.03); evenness (0.02) for *K. erecta* were recorded among HS. The HH recruits with highest richness (1.33); evenness (0.67) for *S. leptocarpa* and least richness (0.01); evenness (0.01) for *C. lanata* was recorded. The HCl recruit with highest richness (0.41); evenness (0.21) was in *C. mucunoides* and least richness (0.05); evenness (0.03) with *I. asarifolia*. The general trend of herbaceous richness and evenness was in the order *HG> HH>HS> HCl* by percentage ratio (49.73:30.00:11.34:8.93) and evenness ratio of 49.42:30.18:11.36:9.04) respectively. The shrubby recruit recorded highest richness (0.16) and evenness (0.08) in *T. eriophlebia* and *S.dulcis*; least richness (0.02) and evenness (0.01) in *T. cordifolia*, *M. subulalus* while shrubby climber (*C. splendense*) in highest richness (0.16); evenness (0.08) and *P. muellerianus* in least richness (0.15); evenness (0.08) were recorded with a varying order of *Sh > ShCl* by the richness ratio of 82.39:17.61 and evenness ratio of 82.41:17.58. A tree life form (*E. guineensis*) with 0.16 richness and 0.08 evenness was recorded. On the whole an herbaceous recruit with richness (23.63); evenness (12.06) and shrubby recruit richness (1.76); evenness (0.91) was recorded.

The pattern of distribution among the regeneration recruits based on abundance: frequency ratio has recorded a highest contiguous pattern with *D. horizontalis* and least distribution (0.07) with B*. falcifera,* random (0.04) with *S. barbata* among HG. The HS highest (1.20) contiguous distribution was in *K. erecta* and least (0.18) in *C. haspan*, The HH had a highest (0.68) contiguous pattern with *O. affinis* and least (0.06) with *C. odorata*. HCl highest contiguous (0.78) in *P. foetida* and least (0.09) in *I. involucrata*. The general trend of herbaceous distribution pattern was in the order *HG> HH>HS> HCl* by the relative ratio of 38.66: 32.71: 17.54: 11.10 respectively. The shrubby recruits had a highest (0.64) contiguous pattern with *Urena lobata* and least (0.10) in regular pattern with *T. eriophlebia* and *M. subulalus*, while shrubby climber (*C. splendense*) in highest distribution (0.24); and *P. muellerianus* with least distribution (0.20) were recorded with a varying order of *Sh > ShCl* by the distribution ratio of 88.39:11.34. On the overall the herbaceous recruits had higher distribution (26.05) pattern than shrubby recruits with 3.88.

iii. Life form regeneration based on environmental adaptation

A total of 78 recruits of herbaceous life form under ecological resilience revealed diverse environmental adaptiveness with 37 (47.44%) Hemi-cryptophytes and 41 (52.56%) Chamaephytes recorded at the p-RENA landscape condition (Table 3). Across the diverse environmental adapted life forms are various composition [10 (12.82%) HG; 1 (1.28%) HS; 15 (19.23%) HH; and11 (14.10%)] HCl of herbaceous Hemi-cryptophytes recorded. Similarly, HG had 14 (17.99%); HS 8 (10.26%); HH 18 (23.08%) and HCl 1 (1.28%) Chamaephytes respectively. Seventeen shrubby life form had 2(11.77%) Mesophanerophytes, 8(47.06%) Microphanerophytes and 5 (29.41%) Nano-phanerophytes, while ShCl had 2 (11.77%) Hemi-cryptophytes with one megaphanerophyte (Tree life form) recorded.

iv. Degree mode of regeneration

Diverse mode of regeneration involving single and multiplier level of regeneration was recorded across the life forms of recruits (Table 3). The HG recorded six levels of regeneration among 24 recruits; 17 recruits recorded multiplier mode and 7 recruits with single level of regeneration recorded with their relative percentage composition across individual HG life form (Table 4). The HS had four levels of regeneration among 9 recruits; six recruits exhibiting multiplier mode and three recruits had single mode of regeneration with their relative percentage composition across individual HS life form. The HH showed four levels of regeneration among 33 recruits; in which 11 recruits had multiplier mode, with 22 recruits having single mode of regeneration with their relative percentage composition across individual HH life form. HCl recorded two levels of regeneration among 12 recruits; six had multiplier and single mode of regeneration respectively with their equal relative percentage composition across individual HCl life form. The shrubby life form recorded has two levels of regeneration among 15 recruits; 3 recruits had multiplier mode and 12 recruits with single mode of regeneration with their relative percentage composition across individual Sh life form. The tree life form had single mode of regeneration. ShCl had two levels of regeneration with each recruits recording a multiplier and a single mode of regeneration respectively.

v. Demographic regeneration status

The demographic status of regeneration with a total of 96 recruits composed of 80 (83.33%) seedling and 16 (16.67%) sapling was maximal at the p-RENA land scape of the study site across the herbaceous, tree and shrubby recruits (Table 3). Two seedlings (*E. tenella* and *C. dactylon*) with highest density (6250ha^{-1}) respectively of the total density (49,600ha^{-1}) among the 23 HG seedlings (Table 3) were recorded. One seedling (*C. iria*) of the HS (9) recruits had highest density (5000ha^{-1}) of the total density (14775ha^{-1}). The HH with 31 recruits had one seedling (*Shrankia leptocarpa*) with highest density (5000ha^{-1}) of the total density (39,600ha^{-1}) of recruits. The HCl recruits recorded one seedling (*C. mucunoides*) with highest density (2500 ha^{-1}) of the total density (10650ha^{-1}). The shrubby (Sh) recruits had one seedling (*D. tortusum*) with highest density (1000 ha^{-1}) of the total density (8625ha^{-1}). Across the seedling status, the HG had the highest seedling density (49,600 ha^{-1}) and HCl least density (10,650ha^{-1}) in the order of *HG> HH>HS>HCl*. Across the Herbaceous life forms one sapling recruit (*Sorghum* *arundinaceum*) with highest density (1375ha^{-1}) of the total density (114,625ha^{-1}) was recorded. The Shrubby sapling recruit had *Triumfetta rhomboidea* with highest density (1125ha^{-1}) of the total density (8625ha^{-1}). Generally the regenerating recruits of the herbaceous life forms had greater seedling density (112, 600ha^{-1}) than sapling density (2,025ha^{-1}) while the shrubby life forms had greater sapling density (6500ha^{-1}) than seedling density (2125ha^{-1}).

4.1. DISCUSSION

The Edovna forest of Umuobizu is one of the ROW low land vegetation landscape adjoining the low land primary and secondary tropical rainforest of Emuoha council area. The floristic classification, structure and composition have revealed successional changes following the anthropogenic impact of crude oil spill and impact of p-RENA treatment. A floristic trend of low land secondary scrub vegetation, mosaic in nature with heterogeneous continuum in spatial and closed horizontal assemblage of structure arrangement was revealed. Successional changes due to ecological alteration by anthropogenic influences across human dominated physiognomic units have been documented [19, 25, 52].

There was variation in the composition of family members of representative species and with the Poaceae having the highest both in abundance and diversity species richness. This corroborates a study recording increased composition among members of the Poaceae in a naturally regenerating disturbed site [53]. The Poaceae in the study site was higher in species richness as compared to other recruitments of the remediated landscape. The reason for such higher species diversity could be variation in abiotic and biotic features and association, which were not considered in this present study. However, research has shown that different intensities of anthropogenic disturbances and local variation in land scape condition can lead to higher number of grass land association [54].

The phytosociological analysis of the habit based life form has revealed variation in terms of species frequency, abundance density; IVI, diversity richness, evenness, and distribution pattern among the various (herbaceous, shrubby, tree and shrubby climber) life forms. The overall phytosociological evaluation in various percentage ratio was higher in herbaceous grass (HG) in the order *HG>HH>HS>HCl* across the indices. However, the HH life form exhibited the highest species richness with 33 of the recruits belonging to different families followed by HG exhibiting species richness with 24 of the recruits belonging to the Poaceae family. Similar level of abundance was revealed in a naturally regenerating disturbed habitat [55]. Attempts have been made to analyse the pattern of species diversity in human dominated landscape [56].

Species diversity plays a vital role in restoration ecology in similar assertion by Magurran [57] in conservation biology. It is one of the important phytosociological index of plant community, a major index connected to conservation dynamics and environmental quality [19, 58]. A change in species diversity is often used as an indicator of anthropogenic or natural disturbances in an ecosystem [58]. Therefore characterization of recruits' diversity through phytosociological inventories can be useful in regeneration study that aims to evaluate and select resilience and tolerant species with demonstrated potential for remediation. In addition, the highest frequency, abundance, density, and hence IVI values were exhibited by different species in the HG life forms. Of the herbaceous life forms of recruits the overall horizontal distribution across life forms represented by the frequency of occurrence of the regenerating recruits was relatively low with 10 species (*Axonopus compressus, Andropogon rapens, Eragrostis ciliaries, Eragrostis tenella, Cynodon dactylon, Schizachyrum brevifolium, Cynodon nlemfuensis, Setaria megaphylla, Setaria barbata,* and *Perotis indica*) of 24 HG recruits, three species (*Cyperus esculentus, Cyperus haspan* and *Cyperus iria*) of 9 HS recruits, nine species (*Zonia latifolia, Shrankia leptocarpa, Chromolaena odorata, Tridax procumbense*, *Euphorbia prostrata, Euphorbia hysopifolia, Melochia pyramidata, Nelsonia canescens*, and *Achyranthes aspera*) of 33 HH recruits and two species (*Calopogonium mucuniodes* and *Diodia sermentosa*) of 12 HCl recruits having 100% frequency value at the p-RENA landscape. One species (*Triumfetta rhomboidea*) of the 15 shrubby recruits and one species (*Elaeis guineensis*) of the tree recruit were respectively 100% and 50% frequency of occurrence. This could imply that the other recruits among the regenerating life form have scarce horizontal distribution across the life forms. This might require further investigation that can assist in the future design of appropriate remediation intervention for the selection of species with demonstrated phytoremediation potentials.

Importance Value Index (IVI) is an important parameter that reveals the ecological significance of species in a given ecosystem [19, 25, 59, 60]. *Eragrostis ciliaries,* and *Cynodon dactylon* of the HG, *Cyperus iria* (HS), *Shrankia leptocarpa* (HH), *Calopogonium mucuniodes* (HCl) and *Triumfetta rhomboidea* of shrubby life form can be considered the most ecologically important regenerating recruits with IVI value range of 3.24 to 10.43 contributed by their high values of frequency, density and abundance. It is pertinent to note that *E. ciliaris* and *C.dactylon* has recorded greater IVI among the most ecologically important regenerating recruits of the p-RENA Edovna landscape, which corroborates an earlier assertion that IVI indicates the dominance of species in a heterogeneous plant community [61].

The class distribution pattern has revealed a more contiguous pattern across regenerating recruits of herbaceous and shrubby life form. Though the general trend of herbaceous distribution pattern was in the order HG>HH>HS>HCl in their relative percentage ratios, *Kyllinga erecta* among regenerating recruit of herbaceous sedge had the highest contiguous distribution pattern among the herbaceous life form which generally had higher distribution pattern than shrubby recruit. However, a least random distribution in HG and least regular pattern in shrubby recruits were also reported. As observed the patterns of distribution among various regenerating recruits across life forms are indicative of their ability to reproduce and establish efficiently in such a remediated site. In a similar assertion the prevalent nature of contiguous distribution unlike random and regular distribution found in very uniform environments has been documented (Edwin-Wosu and Edu, 2013; Edwin-Wosu and Urhobotie, 2022). Also documented was that class distribution of species is a potential and reliable tool to reveal status o population structures, regeneration of species and also predict responses of species to disturbances and resultant changes in population structure [63,64, 65, 66, 67]. There fore as observed from the present study it was evident that the p-RENA Edovna landscape was turning into diverse heterogeneous natural forest again.

The recruited life form based on environmental adaptation of the p-RENA habitat condition has revealed variation across the various life forms with a higher (52.56%) adaptation of Chamaephyte than Hemi-cryptophytes (47.44%). Across the individual herbaceous life forms, the Chamaephytes was in the order of *HH>HG>HS>HCl* (23.08:17.91:10.26:1.28) while Hemi-cryptophytes was in the order *HH>HCl>HG>HS* (19.23:14.10:12.82:1.28). Similarly across the habit-based shrubby life form was a highest composition (47.06%) of Microphanerophytes followed by Nanophanerophytes (29.41%) then Mesophanerophytes (11.77%) and Hemi-cryptophytes (11.77%) while a Megaphanerophytes was revealed by a habit – based tree life form environmental adaptation. The presence of these demographic variation is an indication that the p-RENA landscape was at one time under anthropogenic disturbance such as the oil spill and remediation intervention which can be supported in a similar assertion by Edwin-Wosu and Edu, [19]]; Kalacska *et al*., [68].

Under variant local environmental conditions the existence of species greatly depends on its regeneration [61]. Upon such premise could also suffice in the present findings that the species existence, tolerance, resilience and survival under such hydrocarbon remediated soil depend largely on the mode of regenerating recruits. Regeneration is a critical phenomenon in forest management because it maintains the desired species composition and stocking after disturbances [69]. Study has revealed that through regeneration a degraded land scape can be recruited back to complete forest cover [61]. In the present study several species of diverse life forms were found existing through diverse mode of regeneration. New species were found regenerating and were absent as adult. Greater mode of single level of regeneration than multiplier level of regeneration was exhibited among the life forms through coppicing, stolon, seedling, sapling, rhizome and tuber. The HG exhibited greater multiplier mode while HH had greater single mode of regeneration. The herbaceous lower vascular recruits among the life forms revealed a secondary physiognomic unit, heterogeneous in nature as a result of the regeneration process with few regenerating shrubby recruits. Research has revealed that in tropical pastures new trees may emerge from residual seed bank or from seed dispersal and / or from sprouts arising from roots and stems [70]. Also the occurrence of true forest in a secondary scrub or old-field vegetation due to ability of certain shrubs to coppice and persist through root suckers after forest clearing has been documented [43].

Understanding the demography of recruits is a fundamental challenge that will help achieve restoration goals [71]. Though the demographic status of regeneration was maximal at the p-RENA land scape of the study site across the herbaceous, tree and shrubby recruits in the present study, research has also revealed that forest recovery is a function of demographic status across life form recruits in which seeds arrival on a disturbed site could establish into seedling which grows into adult trees [55]. While many studies have identified seed limitation as a bottle neck for seedling recruitment during forest restoration [72], this goes to affirm the assertion [41, 73, 74, 75] that greater seedling than other demographic status implies new regeneration as observed in the present research. There was variation among the seedling of herbaceous recruits with the HG having greater seedling density across life forms.

However, between the two demographic statuses, the seedling status was greater in density than the sapling status. Variation in demographic status as noted across the above life forms can explain divergent successional trajectories as opined in a similar assertion by Rozendaal *et al*. [76]. Though the demographic status and rate of natural recruits had apparent variation depending on species identity, density size, and life forms in light of the local environmental (p-RENA) land scape condition, it can be deduced in this present study that the success of natural regeneration depends on both the demographic status and rate of establishment of natural recruits.

4.2 CONCLUSION

The result revealed various life forms of 96 different species of genera under 23 families. Twelve families were dominant, with eight very abundant and four in abundance with diverse species richness. Poaceae had the highest phytosociological composition. The habit based life form had diverse representative species among 78 herbaceous, 15 shrubby, 1 tree and 2 shrub climber of regenerating recruits. Other than greater frequency trend recorded by the herbaceous herbs, the herbaceous grass across all phytosociological indices had greater composition of regenerating recruits among the life forms. The life form environmental adaptation revealed greater Chamaephytes with herbaceous herb life form than Hemi-cryptophytes with herbaceous sedge life form. The shrubby life form revealed a higher Microphanerophytes, followed by Nanophanerophytes and Mesophanerophytes, while shrubby climber was represented by Hemi-cryptophytes and tree life form with Megaphanerophyte. The mode of regeneration involved single and multiplier levels with HG recording the highest levels of regeneration. The demographic and density of regenerating recruits has shown the herbaceous life form with greater seedling density ha^{-1} than sapling density. Though such demography had apparent variation it can be concluded in this present study that the success of natural regeneration depends on both the demographic status and rate of establishment of natural recruits.
