Genetic diversity and phylogeneticrelationshipsamong *Jatropha curcas*L. genotypes from eastern India

Abstract:

Genetic diversity and relationships among 31 Jatropha curcas L. genotypes collected from wide geographical range in eastern India ~~was~~ werestudied employing Random Amplified Polymorphic DNA (RAPD) markers.Identified 19 markers produced 139 band in total. Off these 139 bands, 131 bands were polymorphic exhibiting a high polymorphism of 94.24%.Similarity indices estimated on the basis of RAPD primers ranged widely from 0.44 to 0.83 which suggests that these accessions represent genetically diverse population possibly due to predominance of cross pollination and seed source variability. Genotyping data obtained for RAPD primer across collected accessions were used to generate the UPGMA - based phylogenetic tree which shows two major clusters.The cluster I ~~was~~ consisted of 16 genotypes from two states Jharkhand and Odisha (Chotanagpur and Eastern plateau region) while 15 accessions from West Bengal and Bihar (Indo Gangetic plains region) were grouped together in the Cluster II. This ~~is~~ clear alignment of accessions into two different clusters as per geographical regions was~~possibly~~ probablydue to ~~dissimilar~~ differentgrowing conditions in ~~different regions~~the 2 clusters.

Comment [A1]: Please re-write the sentence it is not making sense as a standalone sentence.

Key words: Affinity, molecular characterization, polymorphism, seed oil, variability

1. Introduction

Jatropha curcas Linn. (Family-Euphorbiaceae) plant is remarkable for its drought hardiness, rapid growth, easy propagation, small gestation period, wide adaptability and optimum plant size for convenient seed collection (Jones and Miller, 1991; Francis et al., 2005). Worldwide itisdeemed a promising species for biodiesel production having a high non-edible seed oil content. The Seeds contain 46-58% of oil on kernel weight and 30-40% on seed weight (Subramanian *et al*. 2005). In fact the potentially high yield of oil per unit land area in *J. curcas*is second only to oil palm (Fairless, 2007). Furthermore, the seed oil quality is suitable for production of biodiesel as it contains more than 75% unsaturated fatty acids (Biello, 2009). Apart

from being a potential biofuel crop *J. curcas* has multiple utilities. Preparations of all plant parts, including seeds, leaves and bark are used in traditional medicine and for veterinary purposes. The latex of *J. curcas*~~latex~~ has also been reported to be an abortifacient and is efficacious in dropsy, sciatica and paralysis (Frienvis 2008). It contains an alkaloid similar to quinine in properties called "Jatprophine" which is believed to have anti-cancerous properties and used for external application on skin diseases and rheumatism (Thomas *et al.* 2008). Nath and Dutta (1992) demonstrated the wound-healing properties of 'cur-cain', a proteolytic enzyme isolated from the latex of the plant. Kone-Bamba et al. (1987) reported coagulating effects of the latex on blood plasma. The oil has a strong purgative action and is widely used for skin diseases and to soothe pain. A decoction of leaves is used against cough and as an antiseptic after birth. Extract from all plant parts have insecticidal properties (Grainage and Ahmed 1988).

Limited success has been achieved in worldwide introduction of *J. curcas*for varied purposes due to unreliable and low seed set and oil yields resulting in poor economic returns (Singh et al., 2010).The Species is characterized by variable and unpredictable yield due to unidentified reasons (Ginwal et al., 2004). Cultivation of *J. curcas*involves risk because it is a wild species and no varieties with desirable traits for specific growing conditions are available(Jongschaap et al., 2007). The major constraint in achieving higher quality oil yield of *J. curcas*is lack of information about its genetic variability, oil composition and absence of suitable ideotypes for different cropping systems.Thus, the positive attributes of this plant are also not fully understood in terms of breeding and utilization (Fairless, 2007) which limits its large-scale cultivation and warrants the need for genetic improvement and breeding in the species.

*J. curcas*is a highly cross-pollinated species which is anticipated to contain wide genetic variability offering significant scope for selecting superior genotypes for enhanced productivity. The promise of this valuable crop can only be realized completely through development and release of high yielding variety/clones which needs sufficient information regarding the extent and pattern of genetic variation in *J. curcas* populations. Modern techniques have accelerated characterization of *J. curcas*germplasm at molecular level (Singh et al., 2010; Xu et al., 2012) and even whole genome sequencing is available (Sato et al., 2010). However, information regarding the extent and pattern of genetic variation in *J. curcas*population is limited (Kaushik et al., 2007; Rao et al., 2008; Gairola et al., 2011; Tripathi et al., 2013; Brasileiro et al., 2013). Overall, scanty information on genetic base, genetic makeup and the patterns of genetic diversity

of *J. curcas*is a bottleneck in development of varieties/ clones with superior traits of commerce. Thus, genetic diversity and relationships among 31 genotypes collected from wide geographical range in eastern India was studied employing Ramdom Amplified Polymorphic DNA (RAPD) markers.

2. Material and Methods

2.1 Plant material

Germplasm of 31 genotypes of *J. curcas*collected from different locations of Eastern India in the states of Bihar, Jharkhand, Odisha and West Bengal (Table 1) maintained as a germplasm garden at Institute of Forest Productivity, Ranchi (India) was utilized.

2.2 DNA isolation

Total genomic DNA was extracted from leaves using the CTAB method (Doyle and Doyle, 1987) with minor modifications. 0.5 g of leaves was weighed (mid-rib removed) for each sample and crushed in pre-cooled motor with a pestle using liquid nitrogen. The crushed leaves were put in a tube and 1 ml of extraction buffer was added to each sample. 0.3ul of mercaptoethanol was then added and the tubes were incubated in hot water bath ("Sonar-Associated Scientific Technologies") at 60^0 C for 45 minutes with intermittent shaking every 5 minutes. Tubes were then removed from water bath, cooled and equal volume of chloroform isoamyl alcohol (24:1) was added. The contents were gently mixed and centrifuged in centrifuge unit (Hermle Labortechnik-Z216MK) at 12000 rpm at 4^0C for 10 minutes. This formed three layers upper aqueous layer, middle protein layer and bottom chloroform layer of plant debris. The uppermost layer was carefully transferred to a fresh clean eppendorf tube. To the supernatant 3 µl of RNase was added and the tubes were incubated at 37^0C for 30 minutes. Tubes were then cooled. Chloroform: isoamyl alcohol (24:1) in equal volume was again added and tubes were inverted gently about 30 times. Centrifugation was carried out at 12000 rpm for 10 minutes at 4^0C. Upper layer was carefully transferred to a fresh tube.2/3^{rd} volume of cold isopropanol was then added to the above and was incubated for 10 minutes at room temperature to precipitate DNA. The tubes were then centrifuged at 12000 rpm at 4^0C for 15 minutes. The supernatant was then discarded and the DNA pellet was washed with 70% ethanol for which ice cold ethanol was added and the tubes were spinned at 6000rpm for 3 minutes. The process was repeated twice. Tubes were air dried and DNA was resuspended in 50 µl of TE buffer and stored at -20^0C.

The yield and purity of DNA were measured using UV spectrophotometer (SpectroquantPharo 300 Merck). The purity of DNA was determined by calculating the ratio of absorbance at 260 nm to that of 280 nm.

2.3 PCR amplifications

A set of 25 random decamer oligonucleotides (Bangalore Genei, India) were used as single primers for the amplification of RAPD fragments (Table 2). The G=C content varied from 60-70% while the melting temperature (Tm) was 32-34 ^{0}C.

The RAPD was carried out in themocyler (Gene Amp-PCR System, Applied Biosystems). The cocktail of PCR reaction was prepared in a final volume of 18µl with 1 x PCR buffer, 1.5 mM $MgCl_2$, taq DNA polymerase 0.3 U, 0.2 mM dNTPs, 2 µM of primer, 40 ng template DNA. PCR reaction mixture was loaded into 0.2 ml thin walled clear PCR tubes. The RAPD-PCR was programmed as I-94^{0}C for 5 minutes- Initial denaturation; II-94^{0}C for 1 minute- Denaturation; III-36^{0}C for 1 minute- Annealing; IV-72^{0}C for 2 minutes- Extension; V-72^{0}C for 5 minutes- final extension followed by 4^{0}C for infinity to hold the samples. The steps II, III and IV were programmed to run for 45 cycles.

PCR fragments were separated electrophoretically on 1.5% agarose gel containing ethidium bromide using 1 x TAE buffer. The PCR products were visualized under UV light in a Gel Doc Unit (ULTRACAM). The banding pattern were photographed and stored as digital pictures (Fig. 1). The reproducibility of the amplification was confirmed by repeating experiment as required.

To analyze RAPD data, the total numbers of unique bands were counted for each primer used. The presence or absence of each individual band was recorded for each lane on the gel representing a different plant sample. For this a matrix was created with each sample representing one column and each band in one row. The presence of a band was recorded as a one (1) and the absence as a zero (0). Only clear, unambiguous and reproducible bands were considered for scoring. The RAPD bands obtained from different primers in the clones of *J. curcas* were scored in the form of binary data of 1 and 0 which were put in the form of data matrix. Recorded data was put in a specified format into software for further assessment.

The population genetic diversity parameters like percentage of polymorphic loci (Kimura and crow, 1964), genetic diversity (Nei, 1973), Shannon's Information Index (Lewaontin, 1972) and genetic distance (Nei, 1972) were calculated using Popgene version 1.31 (Yeh et al., 1999). The total genetic diversity (HT), mean genetic diversity within population (HS) and the relative degree of genetic diversity between populations (GST) were measured using Nei's genetic diversity (Nei, 1987).

3. Results and discussion

Information of existing genetic diversity constitutes the basis of genetic improvement programmes and sustainable management of genetic resources. It depends upon multiple factors such as breeding systems, biological characteristics,evolutionary history, and natural selection impart genetic diversity and (Hamrick and Godt1996; Oyundelger et al., 2021). Since variability is a prerequisite for selection for improvement, it is indispensable to detect and document the amount of variation existing within and between the populations. Populations with low genetic variability have a reduced potential to adapt to environmental changes (Ellstrand and Elam, 1993). Therefore, genetic variation is important for the long term survival of a species (Falk and Holsinger, 1991). *J.curcas*being a naturalized species, its ability to grow in varied eco-climatic zones and its wide range of distribution embraces a considerable scope of genetic variation. Characterization of the available germplasm is needed for breeding programs to be efficient (King et al., 2015; Mastan et al., 2012). However, the degree of genetic diversity in and within natural populations in and outside the Centre of origin in poorly studied for the species, hampering domestication of *J.curcas* for large-scale cultivation.

High efficiency and low expense RAPD markers having the capability to scan and detect multiple loci across all the regions of genome have been found highly suited for genetic variation and phylogeny studies in tree species.In the present study RAPD provided large number of reliable and reproducible fingerprint profiles for a collection of 31 accessions of *J. curcas.* However, the availability of unique or rare fragments present in different accessions were limited. The details of RAPD primers, number of amplified products and percentage polymorphism obtained by analyzing primers have been provided in Table 3. 139 band in total ~~with~~ were observed. Off these 131 bands were polymorphic exhibiting a high polymorphism of 94.24% (Figure 1).

The genetic variation statistics for the loci have been summarized in the Table 4. The observed numbers of alleles (Na) ranged from 1.80 to 2.00 with a mean value of 1.94 while the range of the effective numbers of alleles (Ne) was found to be 1.44 to 1.85 with a mean value of 1.64. The Nei's gene diversity (H) was 0.36±0.15 and Shanon's information index (I) was recorded to be 0.53±0.20. Both values are comparatively higher than those reported for RAPD markers in *J. curcas*in earlier studies (Gupta et al. 2008; Raffi et al. 2012). This reflects the heterozygous nature of the population under study. The high value of Shannon's information index in the present study (>0.5) is an indication of the presence of high genetic diversity.Overall the markers were very informative in recording highly divergent genotypes of *J. curcas*from eastern India.

Similarity indices estimated on the basis of 19 primers ranged widely from 0.44 to 0.83 which suggests that these accessions represent genetically diverse population possibly due to predominance of cross pollination and seed source variability (Table 4). The highest genetic distance (0.79) was found between AK6 and JCRCKG that have come from West Bengal and Jharkhand, respectively while the lowest genetic distance (0.19) was there between JCGLBB and JCGLPD, both from Jharkhand. The high diversity revealed by RAPD markers is in agreement with the conclusion that out-breeding plant species retain considerable variability (Hamrick et al 1990). Still in absence of the pedigree data, the higher probability of origin of all such accessions from the same source and eventual distribution to other locations in a region/state cannot be ruled out.

To understand genetic diversity in the germplasm analyzed, genotyping data obtained for all the nineteen RAPD primer across 31 collected accessions were used to generate the UPGMA(Unweighted Pair Group Method with Arithmetic Mean) -based phylogenetic tree which shows two major clusters (Fig. 2). The accessions JBT-45/5 and JBT-45/13 were seen to be at two ends of the phylogenetic tree exhibiting high diversity.The cluster I was consisted 16 genotypes from two states Jharkhand and Odisha (Chotanagpur and Eastern plateau region) while 15 accessions from West Bengal and Bihar (Indo Gangetic plains region) were grouped together in the Cluster II. This is clear alignment of accessions as per geographical regions possibly due to ~~dissimilar~~ different growing conditions ~~in different regions~~. Grouping according to geographical differences has been observed in other studies also (Gohil and Pandya 2008; Gupta *et al.*, 2008; Senthilkumar*et al.*, 2009). The Cluster I formed two sub-clusters with one of

them with accessions only from Jharkhand while the other sub-cluster had accessions both from Jharkhand and Orissa. Cluster II formed three sub-clusters among which one formed of only two accessions JBT-45/12 and JBT-45/13 (Figure 2). The clusters seen in the dendrogram were also analyzed for their genetic distinctiveness. Coefficient of genetic differentiation (Nei 1973) which is the measure of diversity within groups in population genetics was calculated which was 1 indicting that the population in study is highly diverse.

The prior assessments of genetic variations among Jatropha germplasms using molecular markers show the presence of high genetic diversity for the Central and South American regions and insignificant genetic variation from Asia and Africa. The RAPD technique has been used for assessment of genetic diversity for *J. curcas*~~to~~ whichrevealed low to moderate level of genetic diversity of Indian germplasms (Basha and Sujatha, 2007; Reddy et al., 2007; Pamidiamarri et al., 2009; Basha et al., 2009).Several other molecular studies later employing variety of DNA markers have also underlinedwidespread genetic monomorphism and low genetic variability in *J. curcas*Vásquez-Mayorga et al. 2017; Anggraeni et al. 2018; Gangapur et al. 2018; Carneiro et al. 2022).The possible reason may be absence of the anthropogenic and environmental influences in generating genetic variability mainly in the introduced conditions. It seems that adaptive genomic characters imparting tolerance of growth in wide disturbed scenarios have most probably been acquired by the species before its global distribution.Richards *et al.*, (2006) observed that a pronounced phenotypic plasticity is in itself a genotypic trait that allows the plant to respond to different environments through morphological and physiological changes for its survival. Furthermore, a limited stock has been vegetatively and apomictically propagated, since *J. curcas* is known to exhibit apomixis (Bhattacharya et al., 2005). Another reason behind low variability seems to be the introduced nature of *J. curcas* in countries (like India) where these molecular studies have been conducted with limited numbers of accessions in most of the cases.

Variation in genetic diversity within the species is usually related with geographical range, mode of reproduction, mating system, seed dispersal and fecundity. The genetic diversity in the present investigation might be due to geographical difference and seed source variability as well as high level of cross pollination in the species. Gupta et al (2008) have also recorded wide genetic base in RAPD evaluation of 13 Indian accessions from different agroclimatic zones. Likewise Rafii et al. (2012) found accessions from same and near states or regions to be grouped together according to their geographical origin.According to Pamidimarrians Reddy (2014),

Comment [A2]: Odisha?

Comment [A3]: Please add some results from the Table of nei distance and similarity also the value of 1 will only indicate higher similarity whereas 0 will represent lowest genetic distance.

Comment [A4]: Please add reference here

Comment [A5]: Cite reference of the studies

Portuguese seafarers introduced accessions from Mexico and Central America to India through two dispersal routes: one brought *J. curcas* through Africa, Madagascar and finally to India, while the other passed through Spain on its way to India. This may also be a reason for geographical separation of the accessions in these studies.

Comment [A6]: Could this be related to the current germplasm? Or in general?

Conclusion

Estimating genetic diversity isessential to ensure success in the management of genetic resources, planning and adoption of strategies for genetic breeding in promising species like *J. curcas*.RAPD markers with their high level of polymorphism and ability to decipher genetic variability and relationships appeared to be viable system for undertaking such studies in *J. curcas.* In contrast to most studies, we found ample genetic diversity among the analyzed accessions from four states of eastern India indicating that these accessions represent genetically diverse population due to predominance of cross pollination and seed source variability. A clear cut clustering pattern of the accessions as per geographic regions was recorded which may possibly be due to different genetic makeup of the accessions as a result of evolution in markedly different growing conditions.
