

EFFECT OF SEED TREATMENT AND GROWING CONDITION ON THE GERMINATION AND SURVIVALITY OF CUSTARD APPLE (*ANNONA SQUAMOSAL.*) SEEDLINGS

Abstract

The study was carried out during the year 2018-2019 at the Fruit Research Station Imalia and in laboratory of Department of Horticulture, College of Agriculture, Jawaharlal Nehru KrishiVishwaVidyalaya, Jabalpur (M.P.). The experiment was laid out in Factorial Complete Randomized Design (FCRD) replicated thrice. The experiment consist of two factor viz. A- Three growing condition (G_3 - poly house, G_2 -net house, G_1 -open condition) and B- Six seed treatment (S_1 - water soaking, S_2 -Cowurine, S_3 - GA_3 , S_4 - KNO_3 , S_5 -Thiourea, S_6 -Sodium Thiosulphate) having 18 treatment combinations. Observation were recorded on various aspects like days taken to 1st germination, days taken to 50 % germination, height of seedling, girth of stem, number of leaves, fresh weight of shoot and root, dry weight of shoot and root, root length, total length of seedling, number of roots/seedling, survival percent of seedling.

On the basis of present investigation, it is concluded that among the various seed treatments and growing condition, the growing condition of poly house and seed treatment with GA_3 500 ppm have been proved superior with respect to germination, growth and survival of seedling. Among various treatment combinations, G_3S_3 treatment combination (poly house and GA_3 500 ppm) found best over the rest of the treatment combinations with respect to germination parameters like minimum days taken to 1st germination (25.33) days taken to 50% germination (45.66), growth parameter like maximum - height of shoots (25.13cm), girth of stem (3.91mm) and number of leaves 18.91 at 160 DAS respectively, root length(15.13cm), number of roots/seedling(45.12), survival percentage of seedling (89.34%).The G_3S_4 (Polyhouse and KNO_3) was found next best treatment combination in this respect.

Keyword: Custard: Custard Apple, Chemicals, Seed Treatment, Seed Germination and Survivality, Seedlings

INTRODUCTION

Custard apple (*Annona squamosal.*) also known as Sitaphal belongs to the family Annonaceae and is one of the finest fruits introduced in India from tropical America. It is also found in wild form in many parts of India. In India, custard apple occupies an area of 44 thousand ha with production of 367 thousand MT (Anonymous, 2017). It is found growing almost in all the tropical and subtropical regions mostly in wild form. Custard apple is rich source of Carbohydrate, Protein, Fiber and Mineral's like Calcium, Phosphorus, Iron and Vitamin. Custard apple appears to possess potent bioactive principles in most of its plant parts (Fruit, Seed and leaves). The seeds of custard apple have hard endocarp. Due to this hard seed coat, its germination takes longer time 20 days to 6 months in natural conditions.

The use of plant growth regulators in proper concentration with scarification may regulate seed germination and seedling growth behaviour in many fruit crops. Pre-sowing treatment with growth regulator could lead to increase seed germination and enhancement of seedling growth. A low concentration of plant growth regulators may be ineffective. On the other hand, higher concentration may inhibit the growth. Seed without use of growth regulators showed poor response for germination and subsequent growth. Plant growth regulators like GA_3 , IBA, and IAA enhance the germination, growth and survival of seedlings. GA_3 are used for weaking of the seed coat so that the emergence of radical and plumule is positively influenced for root and shoot formation. Thus, there is

Formatted: Indent: First line: 0"

Formatted: Indent: First line: 0"

need to develop a suitable technology for improving germination and subsequent growth of seedlings for budding and grafting on it. Efforts for pre-sowing seed treatment with plant growth regulators (GA₃ and NAA), chemicals (KNO₃, H₂SO₄, micronutrients mixture) and hot water treatment have been made with varying germination and subsequent seedling vigour in various fruit crops (Hore and Sen, 1994 in bael, Ratan and Reddy, 2003 in custard apple, Dhanker and Singh, 1996 in Annona). Chemicals like Thiourea, Potassium nitrate and Sodium Thiosulphate are also used to improve the seed germination. Annonas are mostly grown by seeds either for seedling plants or vegetative propagation. In order to have uniform and prompt germination and to avoid the problem of uneven and irregular germination and to get sapling either for planting or to be used as rootstocks, the seed treatment of custard apple seed is of quite importance.

MATERIAL AND METHODS

The present investigation was carried out at Fruit Research Station, Imalia, Department of Horticulture, College of Agriculture, JNKVV, Jabalpur and Jabalpur (M.P.) during the year 2018-19. The experiment comprised of Factor A (Three Growing conditions) Open condition G₁, Net house, G₂, Poly house and G₃. Factor B (Seed treatment) Water soaking (S₁), Cow Urine (S₂), GA₃ 500 ppm (S₃), KNO₃ 1% (S₄), Thiourea 1% (S₅), Sodium Thiosulphate 250 ppm (S₆) having 18 treatment combinations. The experiment was laid out in poly bags in factorial completely randomized design with three replications. Observations were recorded using standard procedure and statistically analysed.

A. Germination Parameters

- 1. Days taken to start first germination** - Date of emergence of cotyledonary leaves was recorded and calculated from date of sowing.
- 2. Days taken to 50 % germination**- The number of days were counted from the start of germination till 50 % germination.
- 3. Percent of germination**-The percentage of total seeds germination in each treatment was recorded at 60 days after sowing.

$$\text{Germination (\%)} = \frac{\text{No. of germinated seed}}{\text{Total no. of seeds sown}} \times 100$$

B. Growth Parameters

- 1. Height of seedling (cm):** Height was measured from ground level to the tip of opened leaf at 80, 100, 120, 140, 160 (DAS)
- 2. Girth of stem (mm):** The girth of stem was measured with the help of digital vernier calipers just above the ground surface and the average was calculated at 80, 100, 120, 140, 160 (DAS)
- 3. Number of leaves /seedling:** The total number of leaves per seedling was counted and the average was calculated, matured leaves were taken into account at 80, 100, 120, 140, 160 (DAS)
- 4. Survival percent of seedlings**

The survival percentage of each treatment was recorded at 160 days after seed sowing. The survival percentage was calculated by using formula as given below:

$$\text{Survival percentage of seedling} = \frac{\text{No. of seedling survived}}{\text{Total no. of seedlings}} \times 100$$

RESULTS AND DISCUSSION

Days Taken to 1st Germination

The minimum (29.66) days was required for seed germination under G₃ (Poly house) while, it was maximum (55.16) days under G₁ (Open condition). This is due to high temperature and

humidity in poly house which initiated the early germination. Different seed treatment also significantly affected the initiation of seed germination. The minimum days taken to initiate the germination was recorded with S₃ (GA₃ 500 ppm) while, the maximum days in S₁ (water soaking) i.e. seed soaking in water alone. Our results are also in the line of Rajamanickamet *al.* (2002), Ratan and Reddy (2004). The interaction of growing conditions and seed treatment showed significant effect on initiation of seed germination. The maximum days (60.66) days taken to 1st germination of seed were recorded under G₁S₁ (water soaking and open condition) and the minimum (25.33) days taken to initiate germination under the treatment combination G₃S₃ (poly house and GA₃ 500 ppm). It is probably due to the synergistic combination of both the factors. Our results are also in the line of Vermaet *al.*(2019).

Days taken to 50 % germination

The present research reveals that the growing conditions and seed treatment showed significant effect on germination of seed. The minimum days (51.16) were taken to 50% germination under the growing conditions G₃ (Poly house) and maximum (66.61) were taken under the condition G₁ (open condition). Initiation of seed germination was significantly affected by seed treatment. The minimum (53.44) were taken to 50% germination with S₃ (GA₃ 500ppm) while, the maximum days (76.27) in S₁ (water soaking). Our results are also in the line of Rajamanickamet *al* (2002). The interaction effect of growing condition and seed treatment were found to have significant effect on 50% germination. The maximum days (72.00) taken to 50% germination were noted under the treatment combination of G₁S₁ (Open condition and water soaking). However, the minimum days (45.66) taken to 50 % germination were noted under the treatment combination of G₃S₃ (poly house and GA₃ 500ppm). It is probably due to the synergistic combination of both the factors. Our results are also in the line of Vermaet *al.*(2019).

Height of seedling (cm)

Growing condition had significant effect on attaining maximum height of shoots (i.e. 7.40, 8.41, 12.35, 16.33 and 21.33 cm) respectively at 80, 100, 120, 140 and 160 DAS under the growing condition G₃ (poly house). Our result, are also in the line of Ngullie and Biswas (2017). As regards the seed treatment, maximum height of shoots (6.23, 7.06, 8.55, 11.76, and 14.02 cm) was recorded with S₃ (GA₃ 500 ppm) at 80, 100, 120, 140 and 160 DAS, respectively. Basically, Plant height is a genetically controlled character but several studies have indicated that plant height can be increased by application of synthetic plant growth regulators. However, in the present investigation, a significant difference in plant height was noticed by the application of different concentration of GA₃ is known to enhance cell elongation. Our results are also in the line of Singh et al (2002). Interaction effect of growing condition and seed treatment showed maximum height of shoot i.e. 8.26, 9.40, 15.11, 18.91 and 25.13 at 80, 100, 120, 140 and 160 days after sowing, respectively at successive growth period under treatment combination G₃S₃ (poly house and GA₃). Whereas, minimum height was recorded under G₁S₁ (open condition and water soaking). It may be due to synergistic effect of both factors. Our results are also in the line of Verma et al.(2019).

Girth of stem (mm)

Significantly maximum girth of stem (1.11, 2.33, 2.75, 3.14 and 3.42 mm) was recorded at 80, 100, 120, 140 and 160 DAS in G₃ (poly house) whereas, minimum girth under treatment G₁ (open condition and water soaking). As regards seed treatment, the significantly maximum girth of stem (0.91, 2.01, 2.50, 2.82 and 2.85mm) was recorded with S₃ (GA₃ and 500 ppm) and minimum girth of stem was recorded in S₁ (water soaking). Our result is also in the line of Singh *et al.* (2004) and Meena and Jain (2005), Verma et al. (2019). Interaction effect of growing conditions and seed treatment showed significant effect on girth of stem. The maximum girth of stem 1.30, 2.72, 3.01,

3.51, 3.91 was noted under the combination of growing condition and seed treatment G3S3 (poly house and GA₃). Whereas, minimum girth of stem 0.75, 1.73, 2.11, 2.12, 2.53 was noted under the combination of growing condition and seed treatment G1S1 (open condition and water soaking). It may be due to synergistic effect of both factors. Our results are also in the line of finding of Verma et al. (2019).

Number of Leaves /Seedling

The data regarding number of leaves per seedling as influenced by different growing conditions and seed treatment indicated that the maximum mean number of leaves per seedling was produced by the seedlings grown in G3 (poly house) (6.92, 9.47, 11.31, 13.80 and 16.37 at 80,100,120, 140 and 160 days after sowing. Whereas, treatment G1 (water soaking) recorded minimum mean number of leaves per seedling at all the stage of observations. Among different seed treatments, S3 (GA₃ 500ppm) encouraged leaf production and gave significantly maximum (7.38, 9.68, 10.67, 13.54 and 16.25) number of leaves /seedling at 80, 100, 120, 140 and 160 days after sowing respectively. The production of more number of leaves in GA₃ treatments may be due to the vigorous growth and more number of branches induced by GA₃ which facilitates better harvest of sunshine by the plants to produce more number of leaves. Similar findings were also reported by Chandore *et al.* (2016), Thamer HR and AL Falahy (2014). It may be due to synergistic effect of both factors. Our results are also in the line of Verma *et al.* (2019).

Formatted: Font: Italic

Root length (cm)

The growing conditions significantly influenced the mean root length and the maximum (12.127) root length was recorded under conditions G3 (poly house condition) followed by treatments G2 (11.26) and minimum (10.42) in treatment G1 (Control).

The seed treatment also influenced root length of at 160 days after seed sowing. Among the treatments, S3 (GA₃ 500 ppm) recorded maximum (14.12) root length followed by treatment S4 KNO₃ 1% (13.38). The treatment S1 (Control) recorded minimum (9.15) root length of seed.

The data regarding interaction effects showed that the maximum (15.13) root length was recorded under the treatment combination of G3S3 (poly house condition and (GA₃ 500 ppm). The minimum (8.47) was recorded under the treatment combination G1S1 (open condition and water soaking).

Number of roots /seedling

The growing conditions significantly influenced the mean number of roots/seedling and the maximum (40.34) was recorded under conditions G3 (poly house condition) followed by treatments G2 (37.11) and minimum (31.02) in treatment G1 (Control).

The seed treatment also influenced number of roots/seedling at 160 days after seed sowing. Among the treatments, S3 (GA₃ 500 ppm) recorded maximum (39.80) number of roots/seedling followed by treatment S4 KNO₃ 1% (33.89). The treatment S1 (Control) recorded minimum (32.89) number of roots/seedling.

The data regarding interaction effects showed that the maximum (45.12) no. of roots/seedling was recorded under the treatment combination of G3S3 (poly house condition and (GA₃ 500 ppm). The minimum (26.16) was recorded under the treatment combination G1S1 (open condition and control).

Survival Percentage of Seedling

The growing conditions significantly influenced the mean survival percentage of seedling and the maximum (85.28) was recorded under conditions G3 (poly house condition) followed by treatments G2 (82.50) and minimum (76.83) in treatment G1 (Control).

The seed treatment also influenced survival percentage of seedling at 160 days after seed sowing. Among the treatments, S3 (GA₃ 500 ppm) recorded maximum (39.80) survival percentage of seedling followed by treatment S4 KNO₃ 1% (38.32). The treatment S1 (Control) recorded minimum (32.89) survival percentage of seedling.

The data regarding interaction effects showed that the maximum (89.34) survival percentage of seedling was recorded under the treatment combination of G3S3 (poly house condition and GA₃ 500 ppm). The minimum (73.80) was recorded under the treatment combination G1S1 (open condition and control).

CONCLUSION-

On the basis of present investigation ,it is concluded that among the various seed treatments and growing condition, the growing condition of poly house and seed treatment with GA₃ 500 ppm have been proved superior with respect to germination, growth and survival of seedling. Among various treatment combinations, G₃S₃ treatment combination (poly house and GA₃ 500 ppm) found best over the rest of the treatment combinations with respect to germination parameters like minimum days taken to 1st germination(25.33) days taken to 50% germination(45.66), growth parameter like maximum - height of shoots (8.26, 9.40, 15.11, 18.91 and 25.13cm), girth of stem (1.30, 2.72, 3.01,3.51 and 3.91mm) and number of leaves 8.26, 9.40,15.11, 18.91 and 25.13 at 80, 100,120, 140 and 160 DAS, respectively, root length(15.13cm), number of roots/seedling(45.12), survival percentage of seedling (89.34%). The G₃S₄ (Poly house and KNO₃) was found next best treatment combination.
