STUDY ON GENETIC DIVERSITY IN BLACK GRAM (*Vigna mungo* L. hepper)

ABSTRACT

The present study consists of 45 black gram genotypes (including one check variety) were evaluated at Field Experimentation Centre of the Department of Genetics and Plant Breeding, to study genetic variability, heritability, genetic advance, correlation and path coefficient and genetic diversity for 13 quantitative characters. The experiment was conducted by using Randomized Block Design with three replications during Kharif, 2022. Genotype SNTP- 02 (7.44 g), PL-416 (7.35 g), AKU-13-15 (7.26 g), PLU -1016 (7.22g), KC- 153 (7.21g) were found to be superior in seed yield per plant. High GCV AND PCV were observed in number of primary branches, number of clusters per plant and number of pods per plant. Moderate PCV and GCV were observed in number of pods per plants (43.04%), biological yield (33.77), seed yield per plant (30.282), harvest index (25.4). Low PCV and GCV for days to 50% pod setting (6.24%) was observed. Divergence analysis following Mahalanobis (1936) D^2 analysis has revealed presence of substantial amount of genetic diversity among the genotypes. These 45 genotypes were grouped into six clusters by following Tocher's method. Cluster I contain 19 genotypes, while the cluster IV, and VI were mono-genotypic. The maximum inter-cluster distance was observed between Cluster I and V (761.71) and minimum between cluster II and IIV (81.02). The percent contribution towards total genetic divergence revealed that seed yield per plant, biological yield, harvest index had maximum contribution towards divergence in the present material. Thus, these genotypes present in these clusters provide a broad spectrum of variability in segregation and may be used as parents in the future hybridization programme to develop desirable genotypes for grain seed yield improvement in black gram genotypes.

Keywords: GCV, PCV, Variability, Heritability, Genetic Divergence

INTRODUCTION

Pulses, also known as grain legumes, are a great gift from nature and a significant addition to a diet that mostly consists of cereal. In Asia, they represent the main source of protein. They play a crucial role in Indian agriculture. They play a key role in food and are a crucial and important source of dietary protein, especially for the Indian subcontinent's largely vegetarian population. Pulses have roughly three times the amount of high-quality protein found in cereals, making them a more affordable source of protein to combat human protein deficiency. They may be used as fodder and concentrates in cattle husbandry and are especially helpful in treating protein deficiency. Pulses have unique qualities that make them particularly useful in various cropping systems.

Black gram (*Vigna mungo* (L.) Hepper), also known as urd-bean, udand dal, or urad in India, is a short-lived, self-pollinating, diploid ($2n=2x=22$), grain legume crop belonging to the family Leguminosae with a small genome size of 574Mbp (Gupta and Gopalakrishna *et al.*, 2015). It is significant from the perspective of global food and nutritional security. It is a good pulse crop because it does better in every season. The seeds are incredibly nutrient-dense, containing 24–26% protein, 60% carbohydrates, 1.5%

fat, minerals, amino acids, and vitamins. Additionally, it provides a significant amount of lysine for vegetarians and is a fair source of vitamins like thiamine, niacin, and riboflavin, as well as the essential minerals iron and phosphorus. So it is commonly referred to as "poor man's meat". Blackgram is grown as a mixed crop, cash crop, sequential crop besides growing as sole crop under residual moisture conditions, either after the harvest of rice after the harvest of other summer crops under semi irrigated and dry land condition (Parveen *et al.*, 2011). It is still cultivated on marginal lands under rainfed conditions and faces terminal drought which affects its productivity to a great extent. It is mainly grown for human consumption and also used as fodder for cattle and green manure for soil fertility.

Blackgram is consumed in the form of 'dal' (whole or split husked and un husked) or parched. It is the chief constituent of 'papad' and also of bark (special balls) which makes a delicious curry. Seeds are used in the preparation of many popular dishes. Blackgram differs from other pulses in its peculiarity of attaining some mucilaginous pasty character, when ground up with watt. Blackgram has been distributed mainly in tropical to subtropical countries where it is grown in *Kharif* and summer season. It is utilized in various ways where seeds are consumed as source of protein, vitamins and minerals, while plant parts are used as fodder. It is cooked for consumption with roti and rice and also used in making pastes for several south Indian dishes like idly, dosa, vada etc. With a production of 2.42 million tonnes and a productivity of 615 kg ha⁻¹, India leads the world with an area of 37.2 lakhs/ha (Directorate of Economics and Statistics, 2019-2020). It is primarily grown in Maharashtra, Andhra Pradesh, Madhya Pradesh, Uttar Pradesh, Tamil Nadu, Rajasthan, and Karnataka, among other agro-climatic zones of the nation. Blackgram is grown on 7.01 lakh hectares in Uttar Pradesh, where it produces 2.3 lakh tonnes at a productivity of 553 kg per hectare. Blackgram originated in the Indian subcontinent, claims Vavilov. It is suitable for dry land farming and is typically grown as an intercrop with other crops because it is a drought-resistant crop. In terms of area and importance, blackgram is the second-most important pulse crop in India.

The physiological expression and genetic potential of the crop are greatly influenced by the weather conditions, which have a significant impact on crop growth. It is well known that the availability of specific optimum rainfall, solar radiation, temperature, soil moisture, heat units, etc. during different stages of crop growth determines the yield from any given crop or variety. Despite the fact that this crop is more crucial from a nutritional standpoint, there hasn't been a noticeable increase in area or production between 1950–1951 and 2009–2010. To meet domestic demand, India imports about two lakh tonnes of pulses from other nations each year. The demand for grains and legumes is growing in tandem with the increase in global population, and agriculture. Due to the low availability of pulse grains in India (36 g/day/capita versus the minimum requirement of 80 g/day/capita) and the need to maintain the protein-to-calorie ratio in the diet, pulse production is necessary. The primary limitations of blackgram genetic is lack of genetic diversity that can be exploited, lack of ideotypes that are appropriate for various cropping systems, a poor harvest index, susceptibility to biotic and abiotic stresses, and lack of access to high-quality seeds of improved varieties are all factors that need improvement. It is primarily the result of a few parents who have a high degree of relatedness being used repeatedly in crossing programs (Jayamani and Sathya, 2013). The degree and type of genetic variability present in traits that contribute to yield heavily influences the success of yield improvement (Johnson *et al.*, 1955).

MATERIALS AND METHODS

3.5.1 The experimental materials for the present study were procured from Dr. G.M. LAL from Department of Genetics and Plant Breeding, SHUATS during *kharif*-2022. List of genotypes, used in the present study forty-five blackgram genotypes (Table 1) are grown in Randomized Block Design (RBD) with three replications during *kharif*-2022. Design of Experiment is RBD in 3 replications. The recommended doses of fertilizers N: P:K @ 20:40:40 kg/ha were applied. The full dose of P₂O₅ and K₂O and nitrogen were applied as basal dose at the

time of sowing. The observations were recorded on plot basis for days to 50% flowering, days to physiological maturity and seed yield per plot. For rest of the characters the data was recorded on five randomly selected plants from each genotype in each replication leaving first two border rows from all the four sides in order to avoid sampling error.

3.5.2 Quantitative Traits

Days to 50% flowering, Days to 50% pod setting, Days to maturity, Plant height, Number of primary branches per plant, Number of clusters per plant, Number of pod per plant, Pod length, Number of seeds per pod,

Biological yield per plant, Harvest index, Seed index, Seed yield per plant. Data were subjected to analysis of Mahalanobis' D^2 -statistics (Mahalanobis, 1936), and intra-cluster and inter-cluster distance, cluster mean and contribution of each trait to the divergence were estimated as suggested by **Singh and Chaudhary (1985)**. Clustering of genotypes was done by using Tocher's method (**Rao, 1952**). The cluster distance was estimated by the formula given by **Singh and Chaudhary (1977)**.

RESULTS AND DISCUSSIONS

The analysis of variance (Table 2) revealed significant differences among all the 13 characters under study at 1% level of significance. This indicates that the presence of significantly higher amount of genetic variability among the genotypes present in the investigation for all the yield related characters studied. So, there was a sample scope for selection of promising lines from the present gene pool for yield and its components. The presence of large amount of variability might be due to diverse source of materials taken as well as an environmental influence affecting the phenotype. The PCV was higher than the GCV for all the characters under study (Table 3) which indicated that the environmental factors influencing the characters studied. The present findings are in accordance with the findings of Panigrahi *et al.* (2014), Deepshikha *et al.* (2014), Priyanka *et al.* (2016) and Gowsalya *et al.* (2016). High estimates of heritability coupled with high genetic advance as percent of mean was observed for number of clusters per plant (98.301% and 105.841%), number of primary branches (98.01% and 113.665%), number of pods per plant (97.423% and 86.365%), biological yield (95.837% and 66.687%), seed yield per plant (93.37% and 58.287%), plant height (94.93%, 356.517%), respectively suggesting that there was preponderance of additive gene action governing the inheritance of these characters and offers the best possibility of improvement through simple selection. The findings are in agreement with the results of Aftab *et al.* (2018), Kuralarasan *et al.* (2017-2018), Gowsalya *et al.* (2016) and Singhet *et al.* (2014). Genetic divergence in 45 genotypes of blackgram was measured by following Mahalanobis's D^2 statistic. The diversity available in the crop decides the success of any crop improvement programme with manifested objectives. Assessment of divergence in the germplasm is prerequisite to know the spectrum of diversity. Clustering of genotypes following the Tocher's method as described by Rao (1952) led to formation of SIX clusters. In the present investigation, 45 genotypes of blackgram were studied for their genetic diversity by multivariate analysis as per Mahalanobis D^2 statistic (1936) with respect to eleven important quantitative characters. Tocher's method (Rao, 1952) was used for grouping of genotypes using the pairs of combinations of D^2 values. 40-45 genotypes were grouped in to six clusters. Cluster I was biggest and consisted of 35-19 genotypes (Table 4). The cluster II, III and V consisted of 15, 6 and 3 genotypes, respectively. The remaining clusters viz. cluster, IV, and VI were solitary, with one genotype in each of both clusters.

UNDER PEER REVIEW

Intra and Inter Cluster Distances

Intra and inter cluster distance values have been presented in Table 5 and Fig.-2. Intracluster distance was ranged from zero (cluster IV and VI) to 67.46 (cluster V). The highest intracluster distance was recorded in cluster V (67.46) followed by cluster III (63.68) and cluster II (51.99). The high intra cluster distance values revealed the presence of genetic diversity between the genotypes grouped together in those clusters. Hence, there is a lot of scope for exchange of genes among genotypes within these clusters.

From the inter cluster distance values of the six clusters, the highest divergence occurred between cluster I and V (761.71); cluster I and IV (465.11); cluster III and V (441.63); cluster I and III (392.43); cluster V and VI (307.01) suggesting that the crosses involving genotypes from these clusters would give desirable recombination. From the closest inter cluster distance it was concluded that these genotypes were not very distant but couldn't be grouped together based on studied traits. Several authors have suggested that the crossing between the genotypes of clusters with high inter cluster would yield good segregants for selection (Panigrahi *et al.*, 2020, 2014). The inter-cluster distance were greater than the intra-cluster distance revealing that considerable amount of genetic diversity existed among the accessions. The intra cluster distance ranged from 0.00 to 67.46 and the inter cluster distance ranged from 81.02 to 761.71, indicating that the selected genotypes were highly divergent. Minimum intra cluster distance had been recorded with cluster IV and VI (0.00) due to the presence of solitary accession, followed by cluster I (2.32) and cluster III (2.74).

Cluster Means

The data revealed that considerable differences existed among the clusters for most of the characters (Table 6). The cluster I and cluster II showed the dwarf plant height and highest number of seeds per pod, respectively, while cluster III was average for all the traits. Cluster IV was good for biological yield and seed yield per plant. Cluster V was good for four characters *viz.* number of branches per plant, number of clusters per plant, number of pods per plant and pod length. On the other hand, cluster VI (SNTP - 02) was good for earliness for days to 50% flowering, days to 50% pod setting, days to maturity and maximum mean values for seed index, harvest index and seed yield per plant. It was noticed that cluster VI performed better means in Harvest index, Biological yield, Seed yield per plant but no cluster contained at least one genotype with all desirable characters, which eliminated the possibility of directly selecting one genotype for immediate use. Therefore, hybridization programme between the selected genotypes from diverse clusters is essential to combine all the targeted traits to improve phenotypic performance. Percent Contribution of various characters towards genetic divergence. The per cent contribution of thirteen characters studied towards total genetic divergence has been presented in Table 7. Data revealed that seed yield per plant had contributed highest (21.00%) for genetic divergence and subsequently by biological yield (14.54%), harvest index (10.21 %), number of pods per plant (9.81%), number of clusters (8.46%), number of seeds per plant (6.54%) and plant height (6.53%). days to maturity (4.00%).

CONCLUSION

From the present research, it is concluded that analysis of variance showed significant variation to all the characters. Among 45 genotypes, SNTP-02 (7.44) and PL -416 (7.353) genotypes were found to be superior for grain seed yield per hill plant over the check (SEKHAR - 2). High to

moderate estimates of GCV, PCV, high heritability coupled with high genetic advance as percent mean were recorded for number of clusters per plant, number of pods per plant, number of primary branches indicating predominance of additive gene effects and possibilities of effective selection for **genetic** improvement of the characters. High inter-cluster distance was observed between cluster I and V (761.71) as well as between cluster I and IV (465.1) and were most diverse from each other and hybridization between genotypes **present** in these clusters provide a broad spectrum of variability in segregation. **Therefore**, these genotypes may be used as parents in the future hybridization programme to develop desirable genotypes for seed yield improvement in blackgram.

Fig.1:Histogram depicting GCV, PCV, Genetic advance and h^2 for quantitative characters of 45 black gram genotypes.

Table 4: Grouping of 45 blackgram genotypes based on D² values

Cluster Group	No. of genotype	List of genotypes
1 Cluster-I	19	TBG - 104, IPU - 99, PKRU - 03, IC - 106 - 176, VBN -08, VBN - 11- 16, PKGV - 03, LBG - 623, KU - 321, IPU - 94 - 1, AKU - 14 - 02, IPU - 94 - 2, PU - 11 - 14, IPU - 99 - 18, SEKHAR - 2 (CHECK), TU - 99 - 2, UH - 85 - 2, PU - 31 & PLU - 103
2 Cluster-II	15	PL - 416, PDU - 1, BGP - 21- 28, PLU - 856, AKU - 13- 15, IPU - 99 - 16, PLU - 86 -C, JU - 2, BG - 369, DH - 85 - 2, LBG - 628, T9, PLU- 547, TLU- 328 & PLU- 708
3 Cluster-III	6	PLU- 302, AZAD - 1, PLU - 570, LBG - 648, TLU - 32 - 6 & DH - 85 - 5
4 Cluster-IV	1	PLU- 1016
5 Cluster-V	3	KC - 153, ADT - 3 & KU - 96- 14
6 Cluster-VI	1	SNTP - 02

Fig. 2: Dendrogram depicting clustering of blackgram genotypes into 6 clusters

Table5: Average intra and intercluster distance (D^2) values for six clusters in 45 black gram genotypes

Cluster Distances						
	Cluster I	Cluster II	Cluster III	Cluster IV	Cluster V	Cluster VI
Cluster I	24.83	392.43	135.97	465.11	761.71	221.34
Cluster II		51.99	164.36	81.02	137.12	140.76
Cluster III			63.68	177.82	441.63	120.26
Cluster IV				0.00	207.00	222.20
Cluster V					67.46	307.01
Cluster VI						0.00

Table6: Mean values of these six clusters for 13 characters in black gram genotypes

Cluster Means: Tocher Method													
	Days to 50% flowering	Days to 50% pod setting	Days to maturity	Plant height (cm)	Number of primary branches	Number of clusters per plant	Number of pods per plant	Pod length (cm)	Number of seeds per pod	Seed index (g)	Harvest index (%)	Biological yield (g)	Seed yield per plant (g)
Cluster I	43.14	55.16	78.00	37.38	3.43	3.96	12.35	3.83	4.97	3.85	33.30	12.19	3.82
Cluster II	44.87	51.87	64.24	63.61	11.63	10.84	23.04	4.08	6.15	4.31	29.13	23.92	6.92

Cluster IV	46.33	54.00	59.67	81.33	12.53	11.40	12.93	3.69	5.73	5.40	26.82	26.92	7.22
Cluster V	45.78	53.44	63.78	61.82	14.91	15.13	30.38	4.20	5.98	4.83	30.15	23.15	6.95
Cluster VI	40.00	50.00	62.00	50.86	4.73	10.13	25.20	4.03	6.20	6.10	37.31	19.94	7.44

Fig. 2: Cluster diagram depicting intra and inter-cluster distances
(The figure is not exactly to the scale)

Table 7: Per cent contribution towards divergence of 13 different characters of blackgram genotypes

No.	Source	Contribution%	Times ranked 1st
1	Days to 50% flowering	0.30	3
2	Days to 50% pod setting	4.92	49
3	Days to maturity	4.00	40
4	Plant height	6.53	65
5	Number of primary branches	5.76	57
6	Number of clusters per plant	8.45	84
7	Number of pods per plant	9.81	97
8	Pod length	2.30	23
9	Number of seeds per pod	6.54	65
10	Seed index	5.64	56
11	Harvest index	10.21	101
12	Biological yield	14.54	144
13	Seed yield per plant	21.00	208
