

Editor's Comment:

I believe that in its current form the article should not be accepted for two reasons:

- after obtaining a major grade the manuscript should be sent for another review,
- the only table containing the results of the analyses (table 1) is unclear, in the title the authors state that the results concern fresh and frozen samples - does this mean that an average was calculated from them? what is the justification for this? the average values should be appropriately marked to show whether they differ significantly or not, if the values in the table are given in % then after adding up the content of the components we get 164.99% and 166.32% which is of course unrealistic, because the sum of the content of the components should be about 100%.
