

Influence of INM on yield, quality of potato and soil status

Original Research Article

ABSTRACT

An experiment was carried out to study the influence of INM on yield, quality of potato and soil status at Horticulture Research Farm, College of Horticulture, AAU, Anand during the three consecutive years 2020-21, 2021-22 and 2022-23. The experiment was laid out in Randomized Block Design with three replications and ten treatments viz., T₁: 100 % RDF (220:110:220), T₂: 20 t FYM + 100 % RDF (220:110:220), T₃: 75 % RDF + 25 % RDN through FYM, T₄: 75 % RDF + 25 % RDN through VC, T₅: 50 % RDF + 50 % RDN through FYM, T₆: 50 % RDF + 50 % RDN through VC, T₇: 50 % RDF + 50 % RDN through FYM + 1 L Bio NPK consortium/ha, T₈: 50 % RDF + 50 % RDN through VC + 1 L Bio NPK consortium/ha, T₉: 25 % RDF + 50 % RDN through FYM + 1 L Bio NPK consortium/ha + KMB 1 L/ha, T₁₀: 25 % RDF + 50 % RDN through VC + 1 L Bio NPK consortium + KMB 1 L/ha. The treatment T₂ [20 t FYM + 100 % RDF (220:110:220)] recorded maximum tuber weight per plant (487.13 g), tuber yield (434.8 q/ha) and grade "A" tuber (378.9 q/ha) in pooled analysis. Treatments T₇ to T₁₀ received inoculation of Bio NPK consortium showed higher microbial population. Whereas, grade "B" tuber, TSS and soil status after harvest were found non-significant in pooled data.

Key words: FYM; Tuber weight; Grade "A" tuber; Microbial count;

1. INTRODUCTION

Potato (*Solanum tuberosum* L.) belongs to family Solanaceae. Peru- Bolivian region in the Andes (South America) is the centre of origin of potato. Potato is one of the major vegetable crops of the India and occupies an important position among food crops and provides staple food stuff for millions of people of many part of the world. India produces about 60.14 MT of potato from an area of 2.30 Mha with productivity of 27.31 metric tonnes (Anonymous, 2022-23^b)^[2]. Uttar Pradesh is the leading potato producing state and other important states are West Bengal, Bihar, Gujarat, Madhya Pradesh and Punjab. In Gujarat its production is 39.83 MT from an area of 131503 ha with productivity of 30.29 metric tonnes (Anonymous, 2022-23^a)^[1].

Farm yard manure (FYM) influences the physico-chemical as well biological properties of the soil, which in turn improves the soil fertility, provide excellent soil structure, porosity, aeration, drainage, water retention capacity and prevent soil degradation.

potato is a heavy feeder crop so its mostly depend on supply of nutrients (nitrogen, phosphorus, potassium etc.) through chemical fertilizers (Pandit *et al.*, 2018)^[7]. However, with the increment of the price of these chemical fertilizers as well as its issues about environmental hazards, potato cultivation is now required to be shifted to a promising alternative of inorganic nutrition, called integrated nutrient management (INM). INM involves supplies of nutrients from various sources (inorganic and organic) to achieve balanced nutrition covering benefits and curtailing limitations of both the sources. Specifically, it addresses the adverse effects of chemical fertilizers on soil health and crop qualities as well as incorporates the benefits of organic manures to improve soil fertility and crop performance (Keupper and Gegner, 2019^[5]). Nevertheless, a lot of integrated approach have been made for pushing up the production of vegetable crops, however, work done on potato crop is meagre. Therefore, the present investigation was carried out to study the influence of integrated nutrient management on yield, quality of potato and soil status.

2. MATERIALS AND METHODS

The field experiment entitles "Influence of INM on yield, quality and soil status of potato" was laid out during the three consecutive years 2020-21, 2021-22 and 2022-23 at Horticultural Research Farm, College of Horticulture, Anand Agricultural University, Anand, Gujarat, India, during the *Rabi* season. The experiment was laid out with ten treatments *i.e.* T₁: 100 % RDF (220:110:220), T₂: 20 t FYM + 100 % RDF (220:110:220), T₃: 75

% RDF + 25 % RDN through FYM, T₄: 75 % RDF + 25 % RDN through VC, T₅: 50 % RDF + 50 % RDN through FYM, T₆: 50 % RDF + 50 % RDN through VC, T₇: 50 % RDF + 50 % RDN through FYM + 1 L Bio NPK consortium/ha, T₈: 50 % RDF + 50 % RDN through VC + 1 L Bio NPK consortium/ha, T₉: 25 % RDF + 50 % RDN through FYM + 1 L Bio NPK consortium/ha + KMB 1 L/ha, T₁₀: 25 % RDF + 50 % RDN through VC + 1 L Bio NPK consortium + KMB 1 L/ha in a Randomized Block Design with three replications and plot size of 2.70 × 3.20 m. The experiment soil was light alluvial having sandy loam texture with 7.68 pH, 0.46 % organic carbon, 240.00 kg/ha available N, 23.70 kg/ha available P₂O₅, 340.00 kg/ha available K. Potato tuber of Kufri Kyati variety was planted at spacing of 45 × 20 cm. Application of 50 % Nitrogen, 100 % P₂O₅ and 50 % K₂O and all organic manures and Bio NPK consortium with organic manures were applied as basal while 50 % Nitrogen and 50 % K₂O was applied 30 DAP and while KMB was applied at 45 DAS with irrigation.

For yield observation five plants were randomly tagged. Tubers per plants were weighed by weighing balance and after that the average value was calculated. Yield of tuber were recorded in kg per plot separately and converted into q/ha. The quality parameters *i.e.*, TSS estimated by digital refractometer from tuber at final harvest. Potato tuber grade desided according weight of tuber (grade A: >75g, grade B: 25-75g and grade C: <25g). Soil fertility status and microbial count of soil measured at initial and after harvest of the crop. The pooled analysis was conducted in accordance with Panse and Sukhatme (1989)^[8] to examine the average effect of various treatments over time.

3. RESULTS AND DISCUSSION

3.1 YIELD PARAMETERS OF POTATO

3.1.1 Tuber weight per plant (g):

The data pertaining to tuber weight per plant is presented in Table 1. The result showed significant effect during 2020-21, 2021-22 and 2022-23 as well as in pooled analysis. Maximum tuber weight per plant (487.13 g) was recorded with treatment T₂ [20 t FYM + 100 % RDF (220:110:220)] which was at par with treatment T₃, T₄, T₈, T₇ and T₆ in the pooled data.

This might be due to the usage of both organic and inorganic chemical fertilizers, as an organic fertilizer promoted aeration in the soil, focalized root advancement and boosted microbes and biological production in the rhizosphere which also increased the nutrient use efficiency through modification of soil physical condition and resulted in higher total uptake of nutrients because of better root penetration leading to better absorption of nutrients and moisture that ultimately increase tuber weight of plant. Similar result also found by Solanke *et al.* (2009)^[12] and Jaipaul *et al.* (2011)^[3].

3.1.2 Tuber yield (q/ha):

The data pertaining to tuber yield (q/ha) is presented in Table 1. The result showed significant effect during 2020-21, 2021-22 and 2022-23 as well as in pooled analysis. Maximum tuber yield (434.8 q/ha) was observed with treatment T₂ [20 t FYM + 100 % RDF (220:110:220)] but it was at par with T₃ and T₄ in pooled analysis.

This could be ascribed to the use of organic manure and chemical fertilizer, which altered the physical characteristics of the soil to enhance the efficiency of nutrient use and led to a larger total uptake of nutrients due to better root accessibility, which increased nutrient and moisture absorption in plant that lead to more photosynthates in plant [Khurana *et al.* (2005)^[4]]. Resulted increase tuber weight per plant and ultimately increased total yield of potato tuber. Similar observations have been noted by Kushwah and Banafar (2003)^[6], Raghav and Chandra (2005)^[9] and Singh and Rai (2007)^[11] and Singh *et al.* (2018)^[10].

3.2 QUALITY PARAMETERS OF POTATO

3.2.1 Grade “A” tuber (q/ha):

The data pertaining to grade “A” tuber yield by effect of different integrated treatments during three consecutive years 2020-21, 2021-22, 2022-23 and in pooled data are presented in Table 2. The data regarding grade “A” tuber was found significant in three consecutive years and in pooled analysis. Maximum grade “A” tuber yield (378.9 q/ha) was observed with treatment T₂ [20 t FYM + 100 % RDF (220:110:220)] in pooled data and it was found statistically at par with treatment T₃ and T₄ in the pooled data.

3.2.2 Grade “B” tuber (q/ha):

The data pertaining to effect of different integrated treatment on grade “B” tuber yield during three consecutive years 2020-21, 2021-22, 2022-23 and in pooled data are presented in Table 2. The data regarding grade “B” yield was found non-significant result in three consecutive years and in pooled data.

3.2.3 Grade “C” tuber (q/ha):

The data pertaining to grade “C” tuber yield by effect of different integrated treatment during three consecutive years 2020-21, 2021-22, 2022-23 and in pooled data are presented in Table 2. The data regarding grade “C” tuber was found significant in three consecutive years and in pooled analysis. Maximum grade “C” tuber yield (18.3 q/ha) was observed with treatment T₁₀ [20 t FYM + 100 % RDF (220:110:220)] in pooled data and was found at par with T₉ in pooled analysis.

3.2.4 Total soluble solids (°Brix):

The data on total soluble solids (°Brix) influenced by different treatments is presented in Table 3 and results revealed that effect of different treatments on total soluble solids (°Brix) was found non-significant during the years 2020-21, 2021-22, 2022-23 and in pooled analysis.

3.3 SOIL MICROBIAL COUNT AFTER HARVEST OF POTATO

The data pertaining to effect of different integrated treatments on total microbial count (CFU/g soil) after harvest during three consecutive years 2020-21, 2021-22, 2022-23 and in pooled data are presented in Table 4. The result showed that treatments having application of 1 L Bio NPK Consortium/ha + KMB 1 L/ha significantly increased soil microbial count after harvest *i.e.* in treatment T₇ to T₁₀ as compared to rest of the treatments in all the years as well as in pooled result.

The increment of soil microbial population after application of RDF with biofertilizers might be due to favorable rhizospheric micro-environment developed due to root exudates, soil aggregation, decomposition of root cells and organic matter, availability of plant nutrients, and other physical-biochemical processes resulting a higher microbial abundance in soil.^[13]

3.4 SOIL STATUS AFTER HARVEST OF POTATO

The data pertaining to soil status after harvest of crop (OC, P, K, pH, EC and BD) as influenced by different integrated nutrient management treatment are presented in Table 5. The data concerning to the effect of integrated nutrient management treatments on soil status after harvest of crop was found non-significant.

4. CONCLUSION

From the pooled result of three years, it can be concluded that application of 20 t FYM + 100 % RDF (220:110:220) or 75 % RDF + 25 % RDN through FYM or 75 % RDF + 25 % RDN through Vermicompost gave the higher tuber weight per plant, tuber yield and grade “B” tuber with increase microbial population in the soil.

ACKNOWLEDGEMENTS

The Authors are highly thankful to the Anand Agricultural University, Gujarat for firm support, funds and facilities provided.
