

## **Effect of organic farming practices on soil chemical properties**

### **Abstract**

A survey was conducted in Bellary district Northern Dry Zone of Karnataka (zone-3). Only such of those farmers who were practicing it for more than five years were selected and the information on type and quantity of organics used by them in different cropping systems viz., Groundnut, Ragi, Onion, Drumstick and Maize was collected, Soil samples from the selected 30 organic farms and the neighboring conventional farms under the same cropping system were also collected. The results revealed that the organic farming approaches enhance the chemical composition of soil, augment the availability of macro and micronutrients, and elevate the soil's organic carbon status—all of which are critical for sustainable crop yields. It is possible to draw the conclusion that organic agricultural practices positively impact soil characteristics and sustainable yield, hence improving soil health.

**Keywords:** Organic farming, Conventional farming, Cropping system, Nutrient status.

### **1. Introduction**

Prior to the 1960s, when inorganic chemical fertilizers started to gain traction, developing countries customarily and preferentially used organic manures, such as composts, crop residues, animal manures, and green manures. In contrast to organic manures, chemical fertilizers were more readily available and less bulky, making them easier to handle, store, and transport. They outperformed several organic manures in crop response. This was especially true during the so-called "Green Revolution," when high-yielding crop varieties were brought in that responded well to high fertilizer dosages. The use of chemical fertilizers replaced organic based nutrient application in a significant way due to the introduction of high yielding varieties and an expansion in the area under guaranteed irrigation.

In several developing nations throughout the early 1970s, sources of crop nutrients were essentially supplanted by chemical fertilizers. As a result, there was a decrease in the intake of organic manures as well as an excessive and unbalanced use of high analysis fertilizers, which led to further issues with soil fertility like acidity and alkalinity as well as multiple nutrient deficiencies, particularly in secondary and micronutrients, and a complete loss of soil health.

These days, organic farming is gradually becoming more and more popular. Farmers have seen a decline in soil health as a result of careless agronomic techniques. While it is commonly known that adding organic residues and manures can improve soil health, nothing is known about how switching from traditional chemical farming to fully organic farming affects the qualities of the soil. Given that a number of farmers in Karnataka have begun to practice organic farming in recent years, a study was carried out in the farmer's field to determine how the use of organic farming practices has affected the physical, chemical, and biological properties of the soil in various cropping systems. Keeping these facts in mind, the

present investigation was taken up with the following objective. To know the effect of organic farming practices on soil chemical properties

## **2. Material and Methods**

In order to identify the farmers who practice organic farming in the Bellary district of Karnataka's Northern Dry Zone (Zone-3), a survey was carried out with assistance from the Department of Agriculture, NGOs, KVKs, and Extension Workers. Only farmers who had been engaged in this practice for more than five years were chosen, and data regarding the kind and quantity of organic materials they employed in their main agricultural systems was gathered.

### **Location of study area**

The largest of all the agroclimatic zones in the state, zone 3 is primarily found on the black soils of North Karnataka. Its overall area is 48.74 lakh hectares geographically. Its predominant agricultural nature is reflected in the 76.60% of its land area that is under cultivation. The Northern Dry Zone is situated between 300 and 460 meters above mean sea level at latitude 17° 25' N and longitude 76° 05' E. With an average annual rainfall of 613 mm, it is distinguished by the lowest rainfall in the state of Karnataka. Its soils are the most fertile; medium black soils predominate, followed by deep and shallow black soils.

### **Soil sampling**

In the winter of 2020 and 2021, soil samples were taken from 30 organic farms that were chosen and had varying cropping strategies. These farms were located in various taluks of Bellary district, which is in the Northern Dry Zone of Karnataka. To further understand how organic farming affects soil qualities, soil samples from nearby conventional farms that use the same crop/cropping strategy were also gathered and used as a control.

### **Preparation and storing of the soil samples**

The gathered soil samples were shade-air dried. To remove the larger pieces (>2 mm), the air-dried samples were crushed using a wooden pestle and mortar and then run through a 2 mm sieve. The soil samples that had been sieved were used for different chemical analyses and kept in separate, dry, and clean containers.

## **3. Chemical properties of soil**

### **Soil reaction**

Soil pH was determined in 1:2.5 soil:water suspension as described by Jackson (1973) using systronic digital 331 pH meter.

### **Electrical conductivity**

Electrical conductivity of the soil was determined in the 1:2.5 soil to water extract

ratio (Jackson, 1973) by using systronic digital meter 304 and expressed as  $\text{ds}^{-1} \text{ m}$ .

### **Soil Organic carbon**

Organic carbon was estimated by Walkley and Black wet oxidation method (Walkley and Black, 1934).

$$\text{Soil organic carbon (g kg}^{-1}\text{)} = \frac{(\text{Blank TV} - \text{Sample TV}) \times \text{N. of FAS} \times 0.003 \times 1000}{\text{Weight of soil (g)}}$$

### **Cation exchange capacity**

Cation exchange capacity of soils was determined by Ammonium acetate method (Page *et al.*, 1982). Five grams of soil was shaken for five minutes with 33 ml of 1N sodium acetate of pH 8.2 in a stoppered centrifuge tube. The supernatant solution was decanted and extraction was repeated for two more times. Then, the soil was washed with isopropyl alcohol in the same manner to remove excess of sodium adsorbed on the soil exchange complex. The adsorbed sodium was later replaced by ammonium ( $\text{NH}_4^+$ ) by treating the soil with neutral normal ammonium acetate (pH 7.0). The displaced sodium was determined by flame photometer.

### **Available nitrogen ( $\text{kg ha}^{-1}$ )**

Available nitrogen was estimated by alkaline  $\text{KMnO}_4$  method where the organic matter in soil was oxidized with hot alkaline  $\text{KMnO}_4$  solution. The ammonia ( $\text{NH}_3$ ) evolved during oxidation was distilled and trapped in boric acid mixed indicator solution. The amount of  $\text{NH}_3$  trapped was estimated by titrating with standard acid (Subbaiah and Asija, 1956).

$$\text{Available N (kg ha}^{-1}\text{)} = \frac{\text{TV} \times \text{N. of H}_2\text{SO}_4 \times 0.014 \times 100 \times 2.24 \times 10^6}{\text{Weight of soil sample (g)}}$$

### **Available phosphorus ( $\text{kg ha}^{-1}$ )**

Available phosphorus was extracted with sodium bicarbonate (0.5 M) at pH 8.5 (Olsen's reagent) and the amount of P in the extract was estimated by chlorostannous reduced phosphomolybdate blue colour method using spectrophotometer at wave length of 660 nm (Jackson, 1973).

$$\text{Available P}_2\text{O}_5 \text{ (kg ha}^{-1}\text{)} = \frac{\text{Graph ppm} \times \text{Volume of extract} \times \text{Volume made} \times 2.29 \times 2.24 \times 10^9}{10^6 \times \text{Aliquot taken} \times \text{Weight of soil sample}}$$

#### Available potassium (kg ha<sup>-1</sup>)

Available potassium was extracted with neutral normal ammonium acetate and determined using flame photometer (Jackson, 1973).

$$\text{Available K}_2\text{O (kg ha}^{-1}\text{)} = \frac{\text{Graph ppm} \times \text{Volume of extract} \times \text{Volume made} \times 1.20 \times 2.24 \times 10^9}{10^6 \times \text{Aliquot taken} \times \text{Weight of soil sample}}$$

#### Available Micronutrients (mg kg<sup>-1</sup>)

The available iron, zinc, copper and manganese were determined by atomic absorption flame photometer after extracting the soil with DTPA (Diethylene Triamine Penta Acetic acid and AAS method) as described by (Jackson, 1973) and expressed in ppm.

$$\text{Available micronutrients (mg kg}^{-1}\text{)} = \frac{\text{Graph ppm} \times \text{Volume of extractant}}{\text{Weight of soil}}$$

## 4. Result and discussion

### Soil reaction (pH) and electrical conductivity (EC)

The data on soil pH and EC in different cropping systems is presented in Table 1. The results revealed that there was a slight decrease in both soil pH and EC due to organic farming practice. In ground nut based cropping system the mean soil pH and EC values ranged from 7.91 to 7.50 and 0.34 to 0.31 dS m<sup>-1</sup> respectively. The corresponding values for soils of ragi based cropping system was 8.21 to 7.67 and 0.33 to 0.30 dS m<sup>-1</sup> respectively, 8.30 to 8.21 and 0.33 to 0.30 in onion based cropping system, 8.01 to 7.64 and 0.34 to 0.30 dS m<sup>-1</sup> respectively, in drumstick based cropping system; 7.85 to 7.32 and 0.33 to 0.30 dS m<sup>-1</sup> respectively, in maize based cropping system.

The soil pH decreased due to continuous application of FYM due to deactivation of Fe<sup>3+</sup> and Al<sup>3+</sup> by chelating effect and release of basic cation through decomposition of organic manure (Gajanana *et al.*, 2005)

### Soil Organic carbon and cation exchange capacity

The organic carbon content and cation exchange capacity of soils under different cropping systems is presented in (Table 2).

In groundnut based cropping system on an average, the organic carbon content and cation exchange capacity increased from 7.00 g kg<sup>-1</sup> and 13.28 (cmol (p+)/kg) in conventional farm to 8.30 g kg<sup>-1</sup> and 15.50 (cmol (p+)/kg) in organic farm in soil, accounting for an increase of 19.17 and 16.65 per cent in soil. In ragi based cropping system on an average, the organic carbon content and cation exchange capacity increased from 6.60 g kg<sup>-1</sup> and 12.62 (cmol (p+)/kg) in conventional farm to 7.50 g kg<sup>-1</sup> and 14.71 (cmol (p+)/kg) in organic farm in soil, accounting for an increase of 14.91 and 16.65 per cent in soil.

In onion based cropping system on an average, the organic carbon content and cation exchange capacity increased from 6.70 g kg<sup>-1</sup> and 12.81 (cmol (p+)/kg) in conventional farm to 7.40 g kg<sup>-1</sup> and 14.60 (cmol (p+)/kg) in organic farm in soil, accounting for an increase of 10.34 and 13.99 per cent in soil. In drum stick based cropping system on an average, the organic carbon content and cation exchange capacity increased from 6.70 g kg<sup>-1</sup> and 12.91 (cmol (p+)/kg) in conventional farm to 7.40 g kg<sup>-1</sup> and 14.70 (cmol (p+)/kg) in organic farm in soil, accounting for an increase of 10.46 and 13.84 per cent in soil.

In maize based cropping system on an average, the organic carbon content and cation exchange capacity increased from 6.90 g kg<sup>-1</sup> and 13.01 (cmol (p+)/kg) in conventional farm to 7.60 g kg<sup>-1</sup> and 15.00 (cmol (p+)/kg) in organic farm in soil, accounting for an increase of 10.47 and 15.30 per cent in soil. Due to build-up of organic carbon in soil due to continuous application of organic manure and crop residue subsequent decomposition of these residues by higher microbial population, which might have resulted in increased soil organic carbon as reported by Krishnamurthy (2010) where in regular addition of organics such as FYM and compost increased the organic carbon status in soils.

### Available soil nitrogen

The data on available nitrogen (N) content of soils presented in Table 3. All the soils were low in available N status irrespective of type of farming and cropping system.

In groundnut based cropping system, the available nitrogen content on an average, increased from 160.09 to 180.90 kg ha<sup>-1</sup> in these soils. Among the soils of six organic farms, the highest increase of 12.98 per cent. In ragi based cropping system, the average of six soils

indicated an increase in available nitrogen content from 155.99 kg ha<sup>-1</sup> in conventional farm to 177.83 kg ha<sup>-1</sup> in organic farm in these soils. The overall increase in nitrogen content due to organic farming was 14.00 per cent.

The soils from onion based cropping system also showed an increase in nitrogen content from 156.38 kg ha<sup>-1</sup> in conventional farm to 178.28 kg ha<sup>-1</sup> in organic farm soil. In drum stick based cropping system on an average was 16.92 per cent in these soils (152.81 to 178.82 kg ha<sup>-1</sup>) respectively. In maize cropping system, the average of six soils indicated that nitrogen content increased from 156.86 to 178.82 kg ha<sup>-1</sup> in these soils.

The data on available nitrogen (N) content of soil indicated that its values were higher in soils under organic farming than conventional farming, irrespective of cropping system followed. Due to organic matter application is also attributable to the greater multiplication of soil microbes caused by the addition of organic materials which mineralize organically bound N to inorganic form (Bellakki and Badanur, 1997).

#### **Available phosphorus in soil**

The data on available phosphorus content of soils are presented in Table 4. The soils under organic farming accounted for higher amounts than those under conventional farming.

In groundnut based cropping system the available phosphorus content increased from 19.23 kg ha<sup>-1</sup> in conventional farm to 25.78 kg ha<sup>-1</sup> in organic farms in these soils. The per cent increase over conventional farming was 34.21 per cent. In ragi based cropping system, the average of six soils indicated an increase of available phosphorus content due to organic farming from 19.23 to 24.82 kg ha<sup>-1</sup> in these soils, respectively. The average increase in these soils was 29.01 per cent.

In Onion based cropping system, the average of six soils showed an increase in available phosphorus content from 20.19 kg ha<sup>-1</sup> in conventional farm to 27.06 kg ha<sup>-1</sup> in organic farm in these soils. The average increase in these soils was 34.08 per cent. In drum stick based cropping system the average of six farms showed an increase of soil phosphorus content due to organic farming from 20.59 to 28.22 kg ha<sup>-1</sup> in soils, respectively. The overall increase in phosphorus content due to organic farming was 36.98 per cent.

In maize cropping system, the average of six farms indicated an average increase in available phosphorus content due to organic farming from 19.75 to 27.26 kg ha<sup>-1</sup> in these soils, respectively. The average increase in these soils was 38.03 per cent. The results of available phosphorus was increased under organic farming in all the cropping systems compared to conventional farming. Due to FYM application with contribution of P by the organics to the soil available pool and coating of organic material on sesquioxides which reduces the phosphate fixing capacity of soil. Similar observations were also reported by Bharadwaj and Omanwar (1994).

**Table 4. Available phosphorus (kg/ha) in soils under different cropping systems.**

#### **Available potassium in soil.**

The data on available potassium content of soils under different cropping systems is given in Table 5.

In groundnut based cropping system on an average, the available potassium content increased from 223.37 kg ha<sup>-1</sup> in conventional farm to 250.18 kg ha<sup>-1</sup> in organic farms in these soils. The per cent increase over conventional farming was 11.99 per cent. In ragi based cropping system, the average of six soils indicated an increase of available potassium content due to organic farming from 213.04 to 246.01 kg ha<sup>-1</sup> in these soils, respectively. The average increase in these soils was 15.45 per cent.

In onion based cropping system, the average of six soils showed an increase in available potassium content from 217.99kg ha<sup>-1</sup> in conventional farm to 246.33 kg ha<sup>-1</sup> in organic farm in these soils. The average increase in these soils was 13.01 per cent. In drum stick based cropping system the average of six farms showed an increase of soil potassium content due to organic farming from 218.15 to 247.59 kg ha<sup>-1</sup> in soils, respectively. The overall increase in potassium content due to organic farming was 13.64 per cent.

In maize cropping system, the average of six farms indicated an average increase in available potassium content due to organic farming from 217.20 to 247.61 kg ha<sup>-1</sup> in soils, respectively. The average increase in soil was 13.99 per cent. The increase in available potassium in soils of organic farms could be attributed to the direct addition of potassium to the available pool of the soil from FYM and vermicomposts. The beneficial effect of FYM on the available potassium might be also ascribed to the reduction of potassium fixation (Tandon, 1988).

#### **DTPA extractable micronutrients in soil**

The data on DTPA extractable micronutrients content of soils under different cropping systems is given in (Table 6 and 7).

In groundnut based cropping system on an average the zinc, copper, iron and manganese content increased from 0.75, 4.71, 22.15 and 24.65 ppm in conventional farms to 0.98, 6.32, 29.72 and 29.62 ppm in organic farms in these soils, accounting for an increase of 32.29, 34.03, 34.15 and 21.24 per cent respectively. In ragi based cropping system on an average the zinc, copper, iron and manganese content increased from 0.92, 5.24, 17.77 and

26.94, ppm in conventional farms to 1.18, 7.02, 23.81 and 30.98 ppm in organic farms in these soils, accounting for an increase of 28.96, 33.91, 34.15 and 21.24 per cent respectively.

In onion based cropping system on an average the zinc, copper, iron and manganese content increased from 0.73, 4.68, 17.01 and 19.74 ppm in conventional farms to 0.94, 6.26, 21.69 and 22.70 ppm in organic farms in these soils, accounting for an increase of 29.03, 33.65, 30.29 and 14.98 per cent respectively. In drum stick based cropping system on an average the zinc, copper, iron and manganese content increased from 0.63, 4.80, 16.20 and 22.17 ppm in conventional farms to 0.81, 6.44, 18.15 and 25.13 ppm in organic farms in these soils, accounting for an increase of 29.02, 33.99, 12.01 and 13.99 per cent respectively.

In maize based cropping system on an average the zinc, copper, iron and manganese content increased from 0.64, 5.29, 15.41 and 25.83 ppm in conventional farms to 0.83, 7.08, 17.25 and 29.22 ppm in organic farms in these soils, accounting for an increase of 29.94, 33.91, 12.04 and 13.50 per cent respectively. The result revealed that the concentration of available Zn, Cu, Fe and Mn in all the soils, irrespective of type of farming or cropping system was above critical limits. But, however, the soils under organic farming recorded much higher concentration of the micronutrients than soils under conventional farming in all the cropping systems. Due to addition of large quantities of organic manures every year under organic farming practice was the cause for such marked increase in the DTPA- extractable micronutrients. Sharma *et al.* (2000).

## 5. CONCLUSION

From the study, the results indicated that organic farming practices improves the chemical properties of soil, increased available macro and micronutrients status and also increasing organic carbon status of soils, which is essential for sustainable production. It could be concluded that the soil properties and sustainable yield get favorably influenced by organic farming practice which in turn would enhance the soil health.
