

Does the effect of different governance channels depend on the level of development of African countries?

Abstract

The level of development of African States is consistent with the discussions surrounding the need for countries in the region to be fully immersed in practical philosophy. Decision-makers must adopt a coordinated strategy to stimulate the sustainable development of their economy; by incorporating various national plans aimed at encouraging well-being into national governance mechanisms. This paper studies the impact of governance on sustainable development. The Pooled Mean Group (PMG) estimate shows that the development level of African countries is strongly influenced by established institutions. In the short- and long-term, various governance indicators (political, economic, and institutional) have a significant impact on human development and the ecological footprint of countries with high levels of development. On the other hand, they can only significantly stimulate development in countries with a medium level of development in the long term. Much more effort should be made in poorly developed countries to address the shortcomings that limit the implementation of laws and the fulfillment of the obligations of companies, the state, and citizens to ensure sustainable development.

Keywords: Governance, sustainable development, Human Development, Human Ecological Footprint

JEL Classification: G28, O15

1. Introduction

The issues of development, reduction of poverty and inequality, environmental protection, etc. have been a major concern of the African states since they acceded to independence. Despite this stated will, the sustainable development indicators of African countries remain low and much lower than those of other continents. UNDP (2019) notes that inequality in human development across the continent remains high, despite the efforts of some countries. This situation was incomprehensible given the many resources available underground until the advent of the institutional economy, which took place particularly in the last quarter of the 20th century and opened up new avenues. In this regard, the contribution of the quality of governance to achieving sustainable development becomes an issue of global concern (Güney, 2017). Several studies have rightly shown that poor governance is one of the major obstacles to development in Africa (Al Bassam, 2013). However, governance is seen as the "fourth pillar of sustainable development" alongside economic efficiency, social justice, and environmental protection (Pinson, 2006). and that this would constitute a policy of improved and effective protection of biodiversity (Bureau et al., 2020).

While the quality of governance is a fundamental determinant of development, it is less clear how countries can achieve this goal. As noted by Acemoglu and James R. (2012), development requires inclusive institutions that enable broad sections of society to participate in political and economic decisions. The consideration of forms of government increases the challenges for the authorities in African countries when formulating economic policy. Several states have rightly noted this, believing, like Hélène Combe (2016), that this is an imperative

Comment [L1]: noted

for sustainable development and a recognized tool for tackling the development agenda (Iyad, 2019). In other words, it has an important and positive effect on sustainable development, and this strong effect applies to all industrialized and developing countries (Güney, 2016). This means that better governance performance for a country leads to better performance in human development (Keser 2017) or contributes to environmental protection (Nkenfack et al., 2020). Defined by the United Nations World Commission on Environment and Development (WCED) as development "that meets the needs of the present generation without compromising the ability of future generations to meet their own needs", sustainable development is seen as an essential means of realigning the world Movement recognized towards a more inclusive model that seeks to balance the economic, social and environmental conditions that are desirable for both current and future generations (Dhahri and Omri, 2018).

Several empirical studies have analyzed the impact of governance on sustainable development by Omria and Mabroukc (2020). (Güney, 2016); (Glass and Newig, 2016; Ramzy et al., 2019); and concerning its dimensions, in particular environmental quality (Nkenfack et al., 2020; Gani, 2012; Al-Mulali and Ozturk, 2015) and human development (Nandha et al., 2013; Ahmad, 2014; Keser 2017). In some previous studies, the relationship between governance and sustainable development has been individually analyzed in terms of voice and accountability, political stability, government effectiveness, regulatory quality, corruption, or bureaucratic quality. Previous empirical work has only examined the effects of governance on sustainable development as a whole or each of its three dimensions, but not all three in a single framework. However, governance quality is a complex phenomenon that includes various indicators (Kaufmann et al., 2010). Based on the current literature on the need to disclose governance measures to ensure robustness, we consider six measures of good governance in three categories: economic governance (government effectiveness and regulatory quality); political governance (political stability and voice and accountability); and institutional governance (corruption control and rule of law). A recent study on governance and sustainable development show the effectiveness of governance in realigning the economic, environmental, and social components of sustainable development (Omria and Mabroukc, 2020).

Unlike most previous empirical studies, in our work, we consider the level¹ (high, medium, and low) of human development in the analysis. Based on econometric modeling of panel data, we will assess the impact of different governance channels (political, economic, and institutional) on sustainable development indicators (human development and ecological footprint) in Africa.

The rest of the article is organized as follows: Section 2 provides a critical review of previous work. Section 3 presents the econometric methodology and the presentation of the variables. The basic results are presented in section 4. Section 5 concludes and proposes some policy recommendations.

2. Literature review

It is rare today to find a study on a development strategy that does not emphasize the importance of governance. Since the 1990s, governance has been the subject of a great deal of work that provides both convergent and contradictory results, thus prompting reflection on the real impact that its improvement can have.

2.1. Relationship between governance and human development

¹ The HDI ranking of countries depends on fixed thresholds based on distribution quartiles: HDI below 0.550 for low human development; HDI between 0.550 and 0.699 for medium human development; HDI between 0.700 and 0.799 for high human development, and HDI of 0.800 or higher for very high human development.

Comment [L2]: Delete

At the global level, the debate on governance and human development, although fragmented, has intensified. While governance refers to how power is exercised in the management of a nation's affairs and its relations with other nations (ADB, 1999), human development is the expansion of people's choices. Various studies on governance and human development suggest that human development is almost impossible without good governance.

Omria and Mabroukc (2020) extend the previous literature on sustainability by demonstrating the effectiveness of good governance in rebalancing the economic, environmental, and social components of sustainable development. Good economic, political, and institutional governance is considered as a conditional variable that rebalances these three components in the case of 20 MENA economies. Using a simultaneous equation modeling approach over the period 1996-2014, show that political and institutional governance contributes positively to the three components of sustainable development.

keser (2017) studies the relationship between governance indicators and the level of human development. The analysis is conducted in time series on a panel of 33 European Union (EU) candidate countries over the period 2002 to 2012. Their analysis shows that at least three of the governance indicators such as government effectiveness, regulatory quality, and the rule of law have significant positive effects on human development. This means that better governance performance for a country translates into better human development performance.

Ahmad and Saleem (2014) conducted a study to determine governance indicators that significantly affect human development. By comparing the Performance Indices, the correlation coefficient between predicted values, Values Account For (VAF), Root Mean Square Error (RMSE) and Mean Absolute Percentage Error (MAPE), multiple regression, and the Multilayer Perception Model obtained from Kaynar and Yilmaz (2011), for a panel of 168 countries, they show that the effectiveness of government, the control of corruption and political stability are the indicators of governance that have a greater impact on the human development of the countries.

Nandha and Russell. (2013) examine the link between governance quality and human development over the period 1995-2011 for a sample of 186 countries. They consider Kaufman's six indicators as a measure of the quality of governance, and the HDI as a human development index. The results suggest: Firstly, the quality of governance and human development are mutually reinforcing in that the quality of governance has a significant impact on human development and vice versa. Secondly, the magnitude of the impact of human development on the quality of governance is much larger than the impact of governance on human development. Thirdly, the magnitude of the impact of the quality of governance on human development has declined over time; while the impact of human development on the quality of governance has been relatively stable.

Charron et al (2014) map the variation in the quality of governance, for 27 European countries, at the national and regional levels. The governance quality dimension is defined by the level of corruption; government effectiveness, accountability, and protection of the rule of law. There is a strong significant relationship between the quality of the governance index and important socio-economic variables such as Internet availability, GDP per capita, long-term unemployment, or infant mortality rate. Overall, there is significant variation between the quality of governance within countries and between regions within countries. This suggests that a joint and targeted effort to improve the quality of governance in these regions could significantly improve their economic prospects and the lives of their residents.

Aidt (2011) examines the relationship between different indicators of corruption and sustainable development as measured by real investment. He concludes that corruption has a negative effect on sustainable development.

Pradhan and Sanyal (2011) studied the effect of governance on development. Using secondary data. Their sample is divided into two sub-samples, namely high-performing and low-performing states based on the Human Development Index (HDI). Based on empirical evidence, they deduce that governance is the latent factor by which sustained economic growth and high human development are achieved. Their work also proposes that less performing countries can stimulate their development processes in the higher range of human development with a better mechanism of good governance.

Haqand Zia (2009) conducted a study to examine the relationship between pro-poor economic growth and governance in Pakistan for the period 1996-2005. All six of the governance indicators formulated by Kaufmann are included. The empirical evidence shows that good governance in Pakistan can reduce poverty and income inequality. Also, Pakistan needs to implement sound and effective governance to achieve higher growth and the Millennium Development Goals.

Uddin and Joya (2007) focused on the importance of good governance for development. They mentioned that it is not easy to achieve rapid per capita income or improve social indicators without improving good governance. They also conclude that strong, accountable, and effective political institutions are required and that aid agencies need a strong and unique long-term commitment to provide the resources and expertise to support governance reform.

2.2. Relationship between governance and environmental quality

Nkenfack et al. (2020) in their work re-examines the effects of governance and institutions on environmental quality. The latter is captured successively by carbon dioxide emissions (CO_2), methane (CH_4), and nitrous oxide (N_2O) in the countries of the Economic Community of Central African States (ECCAS), and the quality of governance and institutions is measured by Kaufman's six governance indicators. Under the Kuznets environmental curve hypothesis (CEK), the econometric model is inspired by the work of Grossman and Krueger (1991, 1995) and is estimated successively by generalized least squares (GCM) and double least squares with instrumental variables (DMC-IV). Two major results emerge from their work. Firstly, there is a "Pseudo CEK" like an "N" between economic growth and the different types of pollutants. Greenhouse gas (GHG) emissions would then follow a sinusoidal or cyclical trend in ECCAS. Secondly, improved governance would significantly mitigate pollutant emissions in the countries under consideration. Therefore, strengthening governance and improving the quality of institutions will contribute globally to reducing greenhouse gas (GHG) emission levels in ECCAS countries.

Gani (2012), Al-Mulali, and Ozturk (2015) found that political instability damages the environment. Osabuohienet al. (2014) analyze the CEK for a panel of 50 African countries grouped into oil-producing and non-oil-producing countries over the period 1995-2010, including variables such as average values of rule of law, quality of regulation, and governance effectiveness in the analysis. In the sample of oil-producing countries, institutions have a positive impact on the emissions of CO_2 , but an opposite effect on non-producing countries. As we can see, the link is therefore not always virtuous between the quality of institutions and the quality of the environment. In this context, Dryzek(1987) states that democracy is assimilated into a market economy that proposes group interests, and which do not necessarily go in the direction of the search for a better environment.

In the same vein, Desai and Shelley (1998) found in a study of ten developing countries, that corruption is a major source of environmental degradation. Following him, Lahiri-Dutt(2004) and Biswaset al. (2012) show that through the informal sector favored by corruption, polluting firms evade environmental regulations and thus induce environmental

degradation; and Ozturk and Al-Mulali (2015) obtain similar results. In fact, they have also shown that controlling corruption leads to a reduction in emissions of CO_2 .

In the literature, the relationship between governance and sustainability has been examined empirically in terms of rule of law, bureaucratic quality, and corruption. According to the results of the estimates obtained in the study, governance has an important and positive effect on sustainable development. This powerful effect applies to all developed and developing countries (Güney, 2016).

3. Data and methodology

3.1. Data

The empirical study focuses on African countries, grouped into three groups² according to the level of human development. The data mobilized in this study are from secondary sources and cover the period 1996 - 2018. We can explain this relatively short study period because data on governance indicators have only been available in the database (WGI) since 1996. The choice of countries selected by group depends on the level of human development as distributed by the UNDP (2019), and the availability of data on certain variables. These data, of a quantitative nature and from secondary sources, are collected in three macroeconomic databases like : **Global Footprint Network (2019)** for the indicator of the ecological footprint variable; WGI (2019) for the indicators of the governance variable; UNDP (2019) for the Human Development Index and WDI (2019) for the indicators of control variables such as gross domestic product, foreign direct investment, infrastructure, population density, value-added in agriculture and value-added in industry.

3.2. Methodology

Drawing on the work of Nkengfack et al. (2020) and Nandha et al. (2013), the linear model to be estimated is written as follows:

$$y_{it} = \phi_i (y_{it-j} - \theta_i' X_{it}) \sum_{j=1}^{p-1} \lambda_{ij}^* \Delta y_{it-1} + \sum_{j=0}^{q-1} \delta_{ij}^* X_{it-j} + u_i + d_t + \varepsilon_{it} \quad (1)$$

Where is ϕ_i the adjustment coefficient (assumed to be negative), θ_i the vector of long-term coefficients, and Δ the variation between two given dates and y_{it} sustainable development. The latter is measured according to Avom and Fankem (2012) and WWF and Global Footprint Network (2008) by human development which considers the socio-economic dimension of sustainable development and, the ecological footprint considering the environmental dimension. The models to be estimated are written considering the two measures for sustainable development:

Model 1: Sustainable development is measured by the Human Development Index (HDI)

$$\begin{aligned} \Delta idh_{it} = & \phi_i^* (idh_{it-1} - \theta_1^* Gov_{it} - \theta_2^* Pibhts_{it} - \theta_3^* ide_{it} - \theta_4^* \ln \inf r_{it}) + \lambda_1^* \Delta idh_{it-1} + \lambda_2^* \Delta Gov_{it} + \lambda_3^* \Delta Pibhts_{it} + \lambda_4^* \Delta ide_{it} \\ & + \lambda_5^* \Delta \ln \inf r_{it} + \varepsilon_{it} \end{aligned} \quad (2)$$

²Group1: High HDI (09 countries); Group2: Medium HDI (13 countries) and Group3: Low HDI (30 countries)

Model 2: Sustainable development is measured by the ecological footprint

$$\Delta Empréco_{it} = \phi_1(Empréco_{it-1} - \theta_1 Gov_{it} - \theta_2 Pibhts_{it} - \theta_3 \ln Ouvcom_{it} - \theta_4 \ln dpop_{it} - \theta_5 VaAgri_{it} - \theta_6 VaInd_{it}) + \lambda_1 \Delta Empréco_{it-1} + \lambda_2 \Delta Gov_{it} + \lambda_3 \Delta Pibhts_{it} + \lambda_4 \Delta \ln Ouvcom_{it} + \lambda_5 \Delta \ln dpop_{it} + \lambda_6 \Delta VaAgri_{it} + \lambda_7 \Delta \ln VaInd_{it} + \mu_{it} \quad (3)$$

Where The Human Development Index (*idh*), which is the composite indicators of the level of human potential and quality of life, is a combination of three dimensions (RepublickiZavodzarazvoj, 2007): life expectancy at birth, the middle number of years education and the expected number of years of schooling combined into a single education index and economic benefits expressed by production, or Gross Domestic Product (GDP) according to purchasing power:

- General quality of life, expressed by the expected duration of life;
- Literacy, measured by a combination of two indicators: the literacy rate of the adult population (weighted by 2/3 significance) and the total enrollment rate in primary, secondary, and higher education (weighted by 1/3 of the character)
- The standard of living that is economic benefits expressed by production that is Gross Domestic Product (GDP) in terms of purchasing power. The analysis of purchasing power parity allows seeing the differentiation in purchasing power between countries by eliminating differences in the price level. It is most commonly used in international comparisons of GDP and its components.

According to the Living Planet Report (2008), the ecological footprint (*Empréco*) measures the biologically productive area of land and water required to produce the resources that an individual, population or activity consumes and to absorb the waste generated, taking into account current technology and resource management. This area is expressed in global hectares (hag), i.e. hectares with a productivity equal to the global average biological productivity.

- Carbon footprint: The partial carbon footprint is the result of combining a footprint that takes into account carbon dioxide emissions related to the country's productive activities and a footprint that estimates carbon dioxide emissions caused by trade flows of manufactured goods (CO₂ emissions from the manufacture and transport of these goods). CO₂ is the only waste product in the Ecological Footprint.
- Pasture footprint: The partial footprint for pasture land uses the consumption of fodder for the production of the country's livestock, and the estimated quantities of fodder used for the production of e.g. imported or exported live animals or dairy products. The calculation of the footprint for the country's livestock production distinguishes between the quantities of animals produced in tons of meat or heads of livestock, and the crops grown for livestock.
- Partial Forest Footprint: This footprint for forests is the result of aggregating a footprint that takes into account the production of forest products (timber, pulpwood, lumber and fuelwood) consumed by a country each year and a footprint of trade flows of forest products.
- Partial footprint of fisheries areas: This is the result of aggregating a footprint that takes into account the country's fish and shellfish production and a footprint of trade flows of fisheries products.
- Partial footprint of cultivated land: This footprint is the result of combining a footprint of the country's production of agricultural products (food, feed, fibre, oilseeds and rubber) with a footprint of trade flows in agricultural products.

- Partial built-up land footprint: The built-up land footprint reflects the area occupied by human infrastructure, including transport, housing, industrial structures and reservoirs for hydropower

Gov measures the quality of institutions. Asongu and Odhiambo (2019) used three composite indicators for precise quantification: political (*Govpol*), economic (*Govéco*), and institutional (*Govinst*) governance. These three measures are obtained by principal component analysis of Kaufman's six indicators.

This study uses the PCA to aggregate the governance indicators obtained from Kaufmann et al. (2010) into three major composite indicators, namely economic, institutional and political governance. Such an approach to governance aggregation is consistent with recent literature on African governance (Asongu and Nwachukwu 2016a). The technique involves reducing a set of highly correlated variables into an uncorrelated set of small indicators known as principal components (PCs). The PCs reflect a substantial variation in information from the original data set.

In the PCA empirical framework, the six governance indicators are reduced to institutional governance, economic governance, and political governance. (i) Political governance (which comprises voice, accountability, and political stability) is the election and replacement of political leaders. (ii) Economic governance (a composition of regulatory quality and government effectiveness) is the formulation and implementation of policies that provide public goods. (iii) Institutional governance (including the rule of law and the fight against corruption) is the respect by citizens and the state of the institutions that govern the interactions between them.

The criteria for selecting PCs are taken from Kaiser (1974) and Jolliffe (2002). According to the authors, only common factors reflecting eigenvalues greater than one or the average should be retained. The results of the PCA are presented in Tables 1, 2, and 3.

The following elements can be retained in the light of the information criterion:

Political governance (*GovPol*) reflects about 77.21% of the information from political stability and "voice and accountability" with an eigenvalue of 1.54423 in high development countries, 80.25% of the information from the quality of regulation and government effectiveness with an eigenvalue of 1.6049 in medium development countries and 79.80% of the information from changes in the rule of law and corruption-control with an eigenvalue of 1.59601 in low development countries;

Economic governance (*GovEco*) reflects about 91.22% of the information coming from political stability and "voice and accountability" with an eigenvalue of 1.8243 in countries with a high level of development, 92.90% of the information coming from the quality of regulation and government efficiency with an eigenvalue of 1.85792 in countries with a medium level of development and 87.43% of the information coming from changes in the rule of law and corruption-control with an eigenvalue of 1.7487 in countries with a low level of development;

Institutional governance (*GovInst*) reflects about 92.10% of the information from political stability and "voice and accountability" with an eigenvalue of 1.84199 in high development countries, 96.31% of the information from the quality of regulation and government effectiveness with an eigenvalue of 1.9262 in medium development countries and 88.23% of the information from changes in the rule of law and corruption-control with an eigenvalue of 1.76465 in low development countries.

Pibhbt is the growth rate per capita of the gross domestic product per capita. It represents the national production as a percentage of the total population, FDI represents a foreign direct investment. They correspond to total FDI inflows as a percentage of GDP, Infrastructure (*lnInfr*) is captured by the number of telephone lines per 100 inhabitants, Trade openness (*lnOuvcom*) is captured by the volume of trade (exports + imports) as a percentage of GDP, *Eprécois* the ecological footprint. It measures the weight of human activities on our natural environment, *Indpopis* the population density, *Va_Agri* is the added value of agriculture and *lnVa_Indus* is the added value of the industry. «ln" placed before certain variables is the Nerian logarithm. *i* is the individual dimension and the temporal dimension of the panel

The complete list of countries is given in Annex 1. In accordance with the data, the descriptive statistics of the different quantitative variables are summarized in Table 1 and 2, respectively for model 1 and 2; while Tables 3 and 4 list the different correlations between the variables. The correlation matrices of the variables of the two models suggest a strong correlation between some variables.

Source :Authors, from Stata

An analysis of the coefficient of variation shows an overall low dispersion of the variables. The correlation between the different governance channels and sustainable development in Africa is positive. In Table 6, it is 0.3574 for political governance, 0.2632 for economic governance and 0.3597 for institutional governance; while in Table 7, it is 0.3415 for political governance, 0.3588 for economic governance and 0.3421 for institutional governance. This correlation coefficient in itself only explains the dependence between two variables. The coefficient of determination, on the other hand, measures the proportion of variability in Y (respectively X) that is linearly explained by X (respectively Y). In this way, in Table 6, 12.77% of the variability of sustainable development is explained by political governance, 6.92% by economic governance and 12.93% by institutional governance. However, in Table 7, 11.66% of the variability in governance is explained by political governance, 12.87% by economic governance and 11.70% by institutional governance.

In the figure 2 below, the HDI rank is lower than the GDP per capita (PPP US \$) rank, it means that the allocation of resources in the best possible way; that is, their policy of development is not in the function of the entire population, but favors the ruling classes (oil-

exporting countries and similar economies based on the exploitation of natural resources and the mono-cultural economy based on them).

Figure 1: Average evolution by country of HDI, GDP per capita and ecological footprint

Source :Authors

GDP and ecological footprint are indicators of well-being. In other words, the higher the GDP per capita is the higher the consumption and thus the ecological footprint. A high ecological footprint would therefore be a sign of development, of well-being, of "happiness". The graph above also shows the evolution of GDP and ecological footprint on a sample of 52 African countries. We can see that these indicators are evolving in the same direction, but the ecological footprint is below the GDP, because it is an exclusively monetary indicator. Its equivalent is the sum of monetary income distributed to individuals in return for production. Moreover, the GDP cannot be an ecological measure of production. On the other hand, the ecological footprint measures the ecological impact of this production. The ecological footprint allows us to indicate whether the GDP is sustainable or not.

We use the Pooled Mean Group (PMG) analysis method proposed by Pesaran et al. (1999) and Pesaran and Smith (1995). This method has the advantage of being used and the variables are I(0), I(1), or both I(1) and I(0).

4. Results

4.1. Analysis of the relationship between the variables

There is a positive correlation between different governance channels, human development, and environmental quality at all levels of development (see figures 2, 3, and 4). This correlation is much more significant in group 1 countries than in group 2 and 3 countries. The figures below show the linear intensity of the relationship between the different modes of governance, human development, and the ecological footprint through the cloud points and the linear adjustment line.

4.2. Effect of different modes of governance on sustainable development

This paper determines the effect of different governance channels on human development and environmental quality using a macroeconomic approach. The results obtained from the estimation of equations (2) and (3) are presented in tables 8, 9, and 10, which represent the results of groups 1, 2, and 3 respectively. In each table, the first three columns correspond to estimates of the relationship between governance and human development and the last three columns correspond to estimates of the relationship between governance and environmental quality. After controlling the other variables, our results show that: *The level of development is a determinant of the link between the quality of governance and sustainable development.*

Generally, in countries with a high level of development, all governance indicators (political, economic, and institutional) have significant effects on sustainable development in the short and long term, measured in terms of human development and the ecological footprint. Contrarily, in countries with medium and low development levels. Indeed, governance indicators only have a significant impact on their sustainable development in the long term.

*Specifically, a 1% increase in political governance increases the level of long-term human development by **0.055%** in Group 1 countries. However, economic and institutional governance significantly boosts human development (columns 5 and 6) and the ecological footprint. Moreover, all governance channels have positive and significant effects on the ecological footprint in the same period.*

In the long term, the trends are reversed, as the effects of political governance become positive and significant for human development, while those of economic and institutional governance are negative and significant. On the other hand, all these indicators have positive and significant effects on the ecological footprint in the long term. There are, however, some similarities among African countries concerning the foreign direct investment and infrastructure variables. In fact, these two variables have positive and significant effects on long-term human development. But the magnitude of its coefficients is higher in countries at high levels of development than in the other two groups of countries (medium and low level of development).

*Further analysis shows us that political governance has a positive effect in countries with a low level of human development, and a significant effect on human development in the group of countries with a high and medium level of human development. In fact, an improvement in the political governance of one unit leads to an increase in the level of human development of **0.0557 units** in group 1, **0.0423 units** in group 2, and **0.0366 units** in group 3.*

Economic governance has a negative effect on *human development* in group 1 and a positive effect in groups 2 and 3. We find that an improvement in the economic governance of one unit leads to a decrease in the level of human development of **0.971** units in group 1, but an increase of **0.0383** and **0.0341** units respectively in group 2 and group 3. But the effect is not significant whatever the sign. At the same time, it has a negative effect on the Ecological Footprint in Group 1 and a positive sign in Groups 2 and 3.

Institutional governance has a negative effect on *human development* in groups 1 and 3, but a positive effect in group 2. We find that an increase in institutional governance of one unit leads to a deterioration in the level of human development of **0.117 units** in group 1, **0.0108 units** in group 3, and an improvement of **0.0211 units** in group 2. It affects the ecological footprint positively and significantly in groups 1 and 3, but negatively in group 2.

As for the effect of different governance channels on the ecological footprint, the results show a positive effect in groups 2 and 3, but a negative effect in group 3. In contrast to political governance, economic governance has a negative effect on the ecological footprint in groups 2 and 3, but a positive effect in group 1. The ecological footprint is positively and

significantly influenced by institutional governance in groups 1 and 3, and negatively in group 2. The sixth column in Tables 8, 9, and 10 show that when institutional governance increases by one unit, the Ecological Footprint increases by **0.0744** in Group 1, **0.107** in Group 3. However, it decreases by 0.218 in group 2.

Governance channels significantly and positively explain the level of development (human development and environmental quality) in the groups of countries under consideration. The negative effect of certain governance indicators allows us to understand that government has not yet reached an acceptable level that could positively influence the development of some African countries.

The effect of this variable is not significant on the Ecological Footprint although we have a positive sign in Group 1, negative in Groups 2 and 3 (see results in column 6 of Tables 8, 9, and 10). The results of our various analyses are summarized in Tables 8, 9, and 10 below:

5. Conclusion

Ultimately, this paper assesses the impact of governance on sustainable development for three samples of African countries according to their level of development for the period 1996 - 2018. We use two indicators of sustainable development: human development and the ecological footprint. Also, we use three governance channels: political, economic, and institutional governance. The result of the econometric analysis based on the Pooled Mean Group is that in highly developed countries all governance indicators (political, economic, and institutional) have an overall significant impact on sustainable development, measured in terms of human development, short- and long-term ecological footprint. Contrary to countries with medium and low development levels. In Group 1 countries, economic and institutional governance significantly stimulates human development (columns 2 and 3) and the ecological footprint. On the other hand, political governance has a negative and significant impact on human development and the ecological footprint. In the long term, however, the trends are reversed as political governance becomes positive and meaningful for human development. Economic and institutional governance is negative and significant for this indicator. But the same indicators have positive and significant long-term effects on the ecological footprint. However, the impact of economic and institutional governance remains minimal or weak. This weakness may be because (Acemoglu et al., 2012) have a large impact on political

governance. The negative effects of certain variables show that the level of governance has not yet reached an acceptable level to significantly influence sustainable development in all African countries. Since political institutions have a strong influence on the economic and institutional governance that leads to development and environmental protection, their establishment is crucial to address the shortcomings that affect the implementation of laws and compliance with the commitments of companies, governments, and citizens for sustainable development in their countries.
