

# Monetary Policy, Digitalisation and Banking Industry Performance in Nigeria

## Abstract

*In the evolving financial landscape of Nigeria, the interplay between monetary policy and digitalization significantly influences the performance metrics of banks. This study explores the multifaceted impact of these two critical factors on the Nigerian banking sector. Monetary policy, orchestrated by the Central Bank of Nigeria, regulates the economy's money supply, affecting banks' lending behaviors and liquidity. Digitalization, on the other hand, offers a transformative potential for banks to enhance operational efficiency, customer experience, and service delivery through technological advancements. The study examines how money supply, lending rate and digitalization (proxied by mobile cell subscription) affect banks' financial performance, focusing on bank credit and liquid assets, while controlling for inflation and exchange rate variables. It also examines the interaction between digitalization and monetary policy variables on bank performance. Employing an interactive multiple regression model, the study analyzes time series data from 1996 to 2022 sourced from the World Bank. Findings indicate that while stringent monetary policies can constrain bank performance by tightening credit and reducing liquidity, digitalization provides an opportunity for banks to counteract these effects through enhanced efficiency. However, the successful integration of digital technologies is contingent upon adequate investment, regulatory support, and strategic alignment with the banks' core objectives. The study concludes that Nigerian banks must adeptly manage monetary policy fluctuations and leverage digitalization to sustain and enhance performance. These insights could guide policy formulation and strategic decision-making within the banking industry.*

**Keywords:** monetary Policy; digitalisation; bank performance; interactive modeling; inflation, exchange rate.

## 1. Introduction

The interplay between monetary policy and digitalization has become a pivotal factor in shaping the performance of banks. On the one hand, monetary policy, through its influence on interest rates and liquidity, directly impacts bank profitability and lending capacity. Expansionary measures, while stimulating the economy, can compress net interest margins, thus affecting bank earnings (Cruz-García, 2020; Ozili, 2023). On the other hand, digitalization is revolutionizing the banking landscape, offering a pathway to enhanced efficiency and customer engagement. It enables banks to operate with leaner cost structures, automate service production, and reduce the need for physical branches, which collectively contribute to long-term profitability (ALshubiri et al., 2023; Ekinci, 2021). As banks navigate these dual forces, they must balance the immediate effects of monetary policy with the strategic implementation of digital technologies to sustain and improve performance.

The banking industry in Nigeria is currently at a crossroads, facing the dual challenges of adapting to dynamic monetary policies and embracing the digital revolution. The Central Bank of Nigeria's monetary policy, which includes tools such as the Monetary Policy Rate (MPR), Exchange Rate (EXR), and Cash Reserve Ratio (CRR), has a profound impact on the performance of banks. These policies influence the cost of credit and the availability of funds, which in turn affect the banks' profitability and lending behaviours (Ademola, 2022; Olaifa, 2022; Monday, 2024). Concurrently, the rapid digitalization of the banking industry promises enhanced efficiency and customer service but also requires significant investment and strategic shifts. Digitalization impacts banks' operational models, cost structures, and revenue streams, with varying

effects on growth and profitability (Agboola et al., 2019). The interplay of these factors presents a complex scenario for Nigerian banks, necessitating a thorough investigation into how monetary policy and digitalization interactively influence bank performance in a developing economy context. This study aims to unravel the intricacies of this relationship, providing insights that could inform policy decisions and strategic planning for banking institutions in Nigeria. The specific objectives of this study are to:

- analyse the impact of monetary policy and digitalisation on bank credit;
- examine the impact of monetary policy and digitalisation on bank liquid assets;
- investigate the interactive effects of monetary policy and digitalisation on bank performance.

## **2. Theory and Literature Review**

There are several theoretical issues that have postulated what determines bank performance. In Uchendu (1995), the theories of bank performance hinge on solvency and liquidity. This study is anchored on the Shiftability Theory, Anticipated Income Theory, Commercial Loan Theory, and Liability Management Theory.

The shiftability theory posits that bank performance in terms of liquidity, profitability, and solvency are promoted by keeping adequate cash deposit as reserves with the Central Bank, purchase short-term securities through open market operation (OMO), expand loans to consumers and businesses, and invest in government bonds or other long-term securities. **The Anticipated Income Theory states that** bank performance is determined by its ability to obtain repayment of loans since it generates cash flow and provides liquidity for the bank. However, the theory noted that loan repayment is a function of the

anticipated income of borrower and not the type of borrower or how the funds was utilized. Also, the Commercial Loan Theory proposes that for banks to meet their performance expectations, it should focus on short-term self-liquidating loans to finance productive activities such as transportation, agriculture, and manufacturing, which would yield profit and ensure safety of funds. More so, the Liability Management Theory established that bank performance depends on the ability to meet liquidity needs, thus, the theory postulates that banks should use money market instruments (liabilities) alongside bank assets to attain its liquidity targets.

From these theories, it is evident that bank performance could be measured by liquidity and bank asset, which informed our choice of variables. Despite this extensive review of theories, none of these theories have considered the possibility of bank performance being affected by digitalisation, which is changing the banking industry operation globally. Thus, this study extended these bank performance theories by including digitalisation and its interaction with monetary policy indicators to determine their impact on the performance of Nigerian banks, which earlier studies neglected.

Empirically, there are a plethora of studies on the impact of monetary policy on the performance of banks. For instance, Uchendu (1995) used the regression model to establish a strong positive relationship between monetary policy and bank profitability in Nigeria. The study could not have considered the simultaneous impact of digitalisation

since mobile cell subscription was not available in Nigeria as at the time of that study.

Also, Borio et al. (2017) employed data for 109 international banks between 1995 and 2012 in 14 countries to conclude that short-term returns, a monetary policy indicator has a significant positive relationship with bank performance.

Analysing the impact of monetary policy on bank performance during the COVID-19 era, Nguyen et al. (2022) utilised system generalized method of moments (S-GMM) to analyse quarterly bank data for Vietnam. The study reported a strong impact of monetary policy on bank performance, while considering the interaction between balance sheet and COVID-19 pandemic. As innovative as their study, the increasing reliance of banks on digital platforms during and after the COVID-19 era was overlooked, a vacuum that necessitated this study. Other studies on the impact of monetary policy on bank performance include (Udeh, 2015; Mamatzakis & Bermpei, 2016; Nguyen et al., 2017; Altavilla et al., 2018; Bats et al., 2023; Caselli & Figueira, 2023; Lukonga, 2023; Peykani et al., 2023; Anwar et al., 2024; Emekaraonye et al., 2024; Shuja et al., 2024).

### 3. Methodology

- Data

We collected annual time series data that spanned 1996 to 2022 from world development indicator of The World Bank. The data were collected based on availability and consistency to avoid spurious results. The variables for which data was collected are described in Table 1 below.

**Table 1: Data source and variables description**

Variable	Nature of variable	Description	Source
Bank Credit	Dependent	Credit to private sector as a proportion of total asset.	The World Bank <a href="http://www.worldbank.org">www.worldbank.org</a>
Liquid Asset	Dependent	Liquidity to asset ratio	The World Bank <a href="http://www.worldbank.org">www.worldbank.org</a>

Money Supply	Independent	Money supply as a proportion of total reserve	The World Bank <a href="http://www.worldbank.org">www.worldbank.org</a>
Lending rate	Independent	Interest rate on credit	The World Bank <a href="http://www.worldbank.org">www.worldbank.org</a>
Digitalisation	Independent	Mobile cell subscription	The World Bank <a href="http://www.worldbank.org">www.worldbank.org</a>
Inflation	Control	Annual change in price index	The World Bank <a href="http://www.worldbank.org">www.worldbank.org</a>
Exchange rate	Control	Value of Naira to a \$US	The World Bank <a href="http://www.worldbank.org">www.worldbank.org</a>

### - Models

The model for this study is adapted from earlier studies that analysed the impact of monetary policy on bank performance (Uchendu, 1995; Udeh, 2015; Nguyen et al., 2017; Borio et al., 2017; Altavilla et al., 2018; Nguyen et al., 2022; Caselli & Figueira, 2023; Lukonga, 2023; Peykani et al., 2023; Anwar et al., 2024; Emekaraonye et al., 2024; Shuja et al., 2024) with variations in digitalisation incorporated into the model and interactive effects (see models 3 and 4).

$$\text{Bank Credit} = \beta_0 + \beta_1 \text{money supply} + \beta_2 \text{lending rate} + \beta_3 \text{digitalisation} + \beta_4 \text{inflation} + \beta_5 \text{exchange rate} + e_t \quad [1]$$

$$\text{Liquid asset} = \beta_0 + \beta_1 \text{money supply} + \beta_2 \text{lending rate} + \beta_3 \text{digitalisation} + \beta_4 \text{inflation} + \beta_5 \text{exchange rate} + e_t \quad [2]$$

$$\text{Bank Credit} = \beta_0 + \beta_1 \text{money supply} * \text{digitalisation} + \beta_2 \text{lending rate} * \text{digitalisation} + \beta_4 \text{inflation} + \beta_5 \text{exchange rate} + e_t \quad [3]$$

Liquid asset =

$$\beta_0 + \beta_1 \text{money supply} * \text{digitalisation} + \beta_2 \text{lending rate} * \text{digitalisation} + \beta_4 \text{inflation} + \beta_5 \text{exchange rate} + e_t \quad [4]$$

where model 1 examines the impact of monetary policy and digitalisation on bank credit, model 2 analyses the impact of monetary policy and digitalisation on bank liquid asset, model 3 determines the interactive effects of monetary policy and digitalisation (measured by mobile cell subscription) on bank credit and model 4 investigates the interactive effects of monetary policy and digitalisation on liquid asset of Nigerian banks.

#### 4. Results and Findings

The study presents results of econometric analysis that included summary of descriptive statistics, correlation test, regression analysis and post estimation reports for empirical validity.

**Table 2: Summary of Descriptive Statistics**

Variable	Mean	Standard Deviation	Skewness	Kurtosis	Jarque-Bera	Prob.
Bank Credit	11.847	3.050	0.989	3.755	4.115	0.1278
Liquid Asset	30.733	18.978	0.761	2.359	2.502	0.2862
Digitalisation	7.697	0.779	-1.617	4.738	12.354	0.0021
Lending rate	17.213	3.054	0.620	3.889	2.133	0.3441
Money supply	2.285	1.023	-0.073	1.902	1.125	0.5698

Source: Authors' computation from World Bank Data

Table 2 shows the descriptive characteristics of the dependent variable and explanatory variables of our model. The mean values indicate the average scores of the variables over the period under consideration, 1996 to 2022 based on data availability. Average bank credit as a proportion of total asset stood at 11.847%, banks' liquidity to asset ratio averaged 30.733%, with an average of 7.697% annual growth in the number of people with mobile cell subscription, a measure of digitalization in this study. Also, lending rate recorded an average of 17.213%, with inflation rate at 12.884%, exchange rate at ₦203.423/\$ for the period under consideration, and money supply as a proportion of total reserve stood at 2.285%. From the standard deviation estimates, the exchange and liquid assets of banks are the most widely distributed, while other variables appear to be stable for the period. More so, the skewness, kurtosis and Jarque-Bera statistics reveals that digitalization variable (mobile cell subscription) is not normally distributed, while all other variables appear to be independently and normally distributed based on the probability value of the Jarque-Bera estimate.

In Table 3, the study depicts the result of the relationship amongst the variables. Obviously, the correlation coefficients indicate that bank credit is inversely related to bank's liquid assets, which implies that the more credit facility banks give the less they

are likely to have liquid assets. Also, bank credit is negatively related to the lending rate and inflation rate. Again, liquid assets are inversely related to lending rate, as it is related to money supply and exchange rate respectively. And inflation and money supply have a weak negative relationship. In furtherance to this analysis, the exchange rate has a significant positive relationship with liquid assets and digitalization. The study also observes a strong positive association between money supply and digitalization, money supply and liquid assets, money supply and exchange rate. The preliminary results reveal that the variables chosen for the study are empirically related and the relationship among the independent variables would not lead to multicollinearity as revealed by the correlation matrix. So, we proceeded to estimate the regression models for the objectives of the study.

**- Impact of monetary policy and digitalisation on bank credit**

In the first model, we used bank credit as a measure of bank performance and money policy is proxied with money supply and lending rate, mobile cell subscription is used as a measure of digitalisation, and we controlled for inflation and exchange rate, with results presented in the Table 4 below.

**Table 4: Regression Results**

<b>Independent variable</b>	<b>Coefficient</b>	<b>Standard</b>	<b>t-statistic</b>	<b>P-value</b>
-----------------------------	--------------------	-----------------	--------------------	----------------

	error			
Money Supply	-2.093	0.995	-2.105	0.0475
Lending rate	0.047	0.306	0.155	0.8782
Digitalisation	8.433	3.200	2.633	0.0155
Inflation	0.094	0.138	0.686	0.5004
Exchange rate	-0.036	0.017	-2.066	0.0514
Constant	13.181	6.170	2.136	0.0446
Adjusted R-squared	0.59			
F-statistic	4.720			0.0278
Durbin-Watson	1.599			

Dependent variable: Bank Credit

Source: Authors' computation using World Bank Data

Table 4 shows the regression outcome of the impact of monetary policy variables and digitalisation on bank credit in Nigeria. The estimates reveal that monetary policy has mixed effects on bank performance. This result is evident in the coefficients of money supply (-2.093; p-value = 0.04575) and lending rate (0.047; p-value = 0.8782), an indication that money supply has a significant negative impact on bank credit, while lending rate has a positive but statistically insignificant impact on the performance of banks in Nigeria.

More so, digitalisation with a coefficient of 8.433 and p-value of 0.0155 appears to bear a statistical positive impact on bank credit, which implies that access to mobile devices promote access to access, reduces financial exclusion and promote the performance of banks in Nigeria.

Also, bank credit is significantly affected by the exchange rate. The regression estimates reveal that the exchange rate bears an adverse impact on bank credit, this is because as the exchange rate increases, the value of the local currency depreciates, and the credit value is significantly reduced. Thus, banks would prefer to lend in hard currency than in local currency, which is volatile in value and subject to depreciation. In addition, inflation has a positive impact on bank credit, but it is not statistically significant.

From this discussion of results, it is evident that money supply and digitalisation are significant variables that affect bank performance in Nigeria through their credit creation abilities. The adjusted R-squared of the models reveals a good fit of 59%, the F-statistic of 4.720 ( $p\text{-value}=0.0278$ ) shows that at 5% level of significance, the model is adequate. The Durbin-Watson statistic of 1.599 indicates the absence of serial correlation in the model.

To examine whether these variables could have more impact on other banks' performance indicator, the study estimated their impact on liquid assets of banks, and the results are presented in Table 5 below.

**- Impact of monetary policy and digitalization on liquid asset of banks**

In the second model, we used liquid assets to measure of bank performance and money policy is proxied with money supply and lending rate, mobile cell subscription is used as a measure of digitalisation, and we controlled for inflation and exchange rate in the model.

**Table 5: Regression Results**

<b>Independent variable</b>	<b>Coefficient</b>	<b>Standard error</b>	<b>t-statistic</b>	<b>P-value</b>
Money Supply	2.740	1.994	1.374	0.1883
Lending rate	-1.230	1.021	-1.204	0.2460
Digitalisation	-14.712	4.410	-3.336	0.0042
Inflation	-1.853	0.536	-3.461	0.0032
Exchange rate	0.223	0.026	8.403	0.0000
Constant	137.449	48.815	2.816	0.0124
Adjusted R-squared	0.88			
F-statistic	33.225			0.0000
Durbin-Watson	1.672			

Dependent variable: Liquid Asset  
Source: Authors' computation using World Bank Data

In Table 5, the regression estimates are consistent with the earlier findings on bank credit with reference to the mixed effects of monetary policy. As regards how liquid assets of banks are affected by monetary policy indicators, the study found that money supply has a positive effect on liquid asset, which means that the expansive monetary policy would result in more liquid asset for banks, this is consistent with theory. Also, lending rate has an adverse effect on liquid assets, but this effect is not statistically significant. What is more interesting in this result is that access to digital devices bears a significant negative impact on the liquid asset of bank with a coefficient of -14.712 and p-value of 0.0042. This result is justified by the increasing demand for online loans and improved access to digital finance through mobile cell subscription, which could reduce the liquidity of banks. In addition, inflation and exchange rates have significantly

affected bank liquid assets, while the effect of inflation is negative, that of exchange rate is positive.

The adjusted R-squared of the models reveals a good fit of 88%, the F-statistic of 33.225 (p-value=0.0000) shows that at 1% level of significance, the model is adequate.

The Durbin-Watson statistic of 1.672 indicates the absence of serial correlation in the model.

Having established the mixed effects of monetary policy variables on bank performance in Nigeria, it would be novel to estimate the interactions between monetary policy and digitalisation and its effect on bank performance. The essence is to determine whether digitalisation complements or antagonizes monetary policy stands in Nigeria.

F-statistic	23.081			0.0000
Durbin-Watson	1.900			

Dependent variable: Liquid Asset  
 Source: Authors' computation using World Bank Data

To address the third objective of the study, we estimated the interactive effects of each monetary policy variable with digitalisation on **bank** credit and liquid assets. Our results shows that money supply and digitalisation are antagonist in driving bank credit in Nigeria, while lending rate and digitalisation are complementary in their effect on bank credit as shown in Table 6. Estimates in Table 7 reveal that **digitalisation** complements monetary policy indicators to promote banks' liquidity. These later findings are important since banks cannot implement monetary policy without the influence of digitalisation. Unfortunately, earlier studies have neglected this obvious practical gap in literature.

The post estimation tests to validate our models are presented in Figure 1 and **Table A (see appendix)** for normality assumption test and the absence of heteroskedasticity. The Jarque-Bera statistic with estimate of 5.819 and p-value of 0.0545 indicates that at 5% level of significance the models appear to have satisfied the normality assumption. More so, the Breusch-Pagan-Godfrey's test **(see appendix)** with Chi-square value of 0.2298 and p-value of 0.2526, established that the models are free from heteroskedasticity and therefore, are homoscedastic.

## **5. Conclusions and Policy Implications**

This study examined the impact of monetary policy and digitalisation on banking sector performance in Nigeria. The aim of this study was to establish whether the interaction between digitalisation and monetary policy is complementary or antagonistic for Nigerian banks, these gaps have been disregarded by earlier studies despite its plausible policy implications.

Using multiple regression analysis, the study established that monetary policy indicators have mixed impact on various measures of bank performance. First, the study arrived at the conclusion that money supply has a negative impact on bank credit but bears a positive impact on banks' liquid assets in Nigeria. The positive impact of money supply on bank performance corroborates earlier findings (Udeh, 2015; Mamatzakis & Bermpei, 2016; Nguyen et al., 2017; Altavilla et al., 2018; Bats et al., 2023). Second, lending interest rate promotes bank credit but hurts banks' liquid assets. The positive impact of lending interest rate on bank performance agrees with earlier studies (Caselli & Figueira, 2023; Lukonga, 2023; Peykani et al., 2023; Anwar et al., 2024; Emekaraonye et al., 2024; Shuja et al., 2024). Third, digitalisation is significant driver of bank credit, and it hinders banks liquid assets in Nigeria. Fourth, digitalisation complements lending rate to promote bank credit and liquid asset respectively. Based on the conclusions established above, the study suggests that banks should constantly interact with monetary authorities and digital firms to ensure that the level of money supply, lending rate and mobile cell subscription growth are not harmful to banks credit and liquid assets. Also, banks can create more credit by leveraging digital technologies through awareness creation on online credit eligibility and availability.
