

TENOFOVIR INDUCED OSTEOPENIA IN HIV PATIENTS: A CASE STUDY

ABSTRACT:

Tenofovir, a nucleotide reverse transcriptase inhibitor, is a key component of highly active antiretroviral therapy (HAART) for HIV infection. While effective in suppressing viral replication, long-term use of tenofovir has been associated with adverse effects, including bone mineral density (BMD) loss and increased risk of osteopenia and osteoporosis. Tenofovir-induced osteopenia is a significant concern in the management of HIV-infected individuals, as it can lead to increased fracture risk and reduced quality of life.

We present the case of a 40-year-old female patient with HIV who was on a Tenofovir disoproxil fumarate (TDF)-containing regimen consisting of Tenofovir disoproxil fumarate, lamivudine, and dolutegravir (TLD) for 8 months and developed symptoms suggestive of osteopenia. The patient presented with difficulty in walking, knee pain and swelling, hip joint pain, and limited left arm mobility, which had significantly impacted her daily activities, leading to her being bedridden for two months. Laboratory findings revealed reduced BMD in the lumbar spine and femoral neck, along with low serum vitamin D levels, supporting the diagnosis of tenofovir-induced osteopenia. The management of tenofovir-induced osteopenia involves discontinuation of TDF and initiation of alternative antiretroviral therapy, as well as supplementation with calcium and vitamin D. In this case, the patient was switched to abacavir, lamivudine, and dolutegravir, which are not associated with significant bone-related side effects. Calcium and vitamin D supplementation were also prescribed to improve bone health. This case highlights the importance of monitoring bone health in patients on TDF therapy and prompt recognition and management of osteopenia to prevent further bone loss and improve quality of life in these patients. Regular assessment of BMD and serum vitamin D levels is essential to detect osteopenia early and initiate appropriate interventions.

Keywords: Tenofovir, osteopenia, antiretroviral therapy, HIV, bone mineral density.

Introduction: Tenofovir, a nucleotide reverse transcriptase inhibitor, is a key component of highly active antiretroviral therapy (HAART) for HIV infection. While effective in suppressing viral replication, long-term use of tenofovir has been associated with adverse effects, including bone mineral density (BMD) loss and increased risk of osteopenia and osteoporosis.¹ Tenofovir-induced osteopenia is a significant concern in the management of HIV-infected individuals, as it can lead to increased fracture risk and reduced quality of life.²

Etiology: The etiology of tenofovir-induced osteopenia is multifactorial, involving both direct and indirect effects of the drug. Direct effects include inhibition of osteoblast function and stimulation of osteoclast activity, leading to imbalanced bone remodeling.³ Indirect

effects include renal tubular dysfunction, phosphate wasting, and secondary hyperparathyroidism, which disrupt normal bone metabolism.⁴ Other factors such as age, sex, race, and concomitant use of other medications may also influence the development of osteopenia in individuals taking tenofovir.⁵

Epidemiology: The prevalence of tenofovir-induced osteopenia varies depending on the population studied and the duration of tenofovir exposure. Studies have reported prevalence rates ranging from 10% to 40% in HIV-infected individuals receiving tenofovir-containing regimens.⁶ Risk factors for the development of osteopenia in this population include older age, female sex, low body mass index, and preexisting bone disorders.⁷

Pathophysiology: The exact pathophysiology of tenofovir-induced osteopenia is not fully understood. However, several mechanisms have been proposed, including direct effects on bone metabolism and indirect effects mediated through the kidney.⁸ Tenofovir is known to inhibit osteoblast function and promote osteoclast activity, leading to accelerated bone resorption and reduced bone formation.⁹ Additionally, tenofovir is associated with proximal renal tubular dysfunction, resulting in phosphate wasting and secondary hyperparathyroidism, which further contributes to bone loss.¹⁰

Clinical Manifestations: Tenofovir-induced osteopenia is often asymptomatic in the early stages. However, as bone mineral density decreases, individuals may experience symptoms such as bone pain, fractures (especially in the hip, spine, and wrist), and height loss due to vertebral compression fractures.¹¹ These symptoms can significantly impact quality of life and mobility in affected individuals.

Diagnosis: Diagnosis of tenofovir-induced osteopenia is based on a combination of clinical assessment, bone mineral density (BMD) measurements, and laboratory tests. BMD can be assessed using dual-energy X-ray absorptiometry (DXA), with osteopenia defined as a T-score between -1.0 and -2.5 standard deviations below the young adult mean.¹² Laboratory tests may reveal abnormalities such as elevated serum alkaline phosphatase, parathyroid hormone, and urine N-telopeptide, reflecting increased bone turnover.¹³

Treatment: The management of tenofovir-induced osteopenia involves a combination of lifestyle modifications, pharmacologic therapy, physiotherapy and monitoring. Lifestyle modifications include regular weight-bearing exercise, adequate calcium and vitamin D intake, smoking cessation, and moderation of alcohol consumption.¹⁴ Pharmacologic therapy may include bisphosphonates, denosumab, or teriparatide, which are used to reduce the risk of fractures and improve bone density.¹⁵ Regular monitoring of BMD and clinical symptoms is essential to assess treatment efficacy and adjust therapy as needed.¹⁶

CASE DETAILS:

A 40 years old female patient who is a known case of retroviral disease on tenofovir disoproxil (TDF), lamivudine and dolutegravir (TLD) treatment since 8 months came to the hospital with the complaints of difficulty in walking associated with knee pain and swelling, hip joint pain since 4 months , unable to grab objects , walking with the help of a stick and cannot lift left hand above shoulder level . The patient was bedridden since 2months unable to do work by herself. Patient was started on TLD regimen 8 months ago when the CD-4 count was 184 and then started to develop knee pain. On examination the patient was conscious and coherent, temperature-afebrile, blood pressure 120/70mmhg, pulse rate 82 beats per minute, cardiovascular system had S1 S2 +, respiratory system had bilateral air entry ,per abdomen was soft , oxygen saturation was 98 percent , central nervous system had no abnormal defects and body mass index of 28.1kg/m². The laboratory findings were the haemoglobin level was 12.8 gm/dl, white blood cell count was 4.8 k /cumm, red blood cell count was 4.56*10⁶/cumm, platelet count was 1.78 lk/cumm, CD4 count 420, T score 3.3, Z score 2.9, serum calcium was 9.8, vitamin B12 was 258, vitamin D 23.7. The ultrasound showed the patient has a small kidney with grade 3 recurrent pyogenic cholangitis (RPC). X ray was conducted in the lumbar spine (0.631g/cm², T- SCORE -2.7) and femoral neck (0.804 g/cm², T -score -2.5) revealed reduced bone mineral density. Based on the complaints and the laboratory findings the patient was diagnosed with tenofovir induced osteopenia. The treatment given to the patient was tablet abacavir 300 mg per oral twice a day, tablet lamivudine 150 mg per oral twice a day, tablet dolutegravir 50 mg per oral twice a day, tablet calcium per oral once a day and tablet multivitamin/b-complex per oral once a day.

Discussion:

In this case, a 40-year-old female patient with HIV presented with symptoms suggestive of osteopenia after being on a TLD regimen for 8 months, including tenofovir disoproxil, lamivudine, and dolutegravir. She complained of difficulty in walking, knee pain and swelling, hip joint pain, and limited left arm mobility, which had significantly impacted her daily activities, leading to her being bedridden for two months.

The patient's laboratory findings revealed a CD4 count of 420, indicating good immunological status. However, her bone health was compromised, as evidenced by reduced bone mineral density in the lumbar spine and femoral neck, indicating osteopenia. Other findings, such as low serum vitamin D levels, also contributed to her bone health issues.

Tenofovir-induced osteopenia is a well-known side effect of TDF, particularly in patients with HIV. The exact mechanism involves TDF's impact on bone metabolism, leading to

increased bone resorption and decreased bone formation. Risk factors for TDF-induced bone loss include long duration of TDF therapy, older age, female gender, low body weight, and vitamin D deficiency.

Management of TDF-induced osteopenia includes discontinuation of TDF and initiation of alternative antiretroviral therapy, as done in this case by switching to abacavir, lamivudine, and dolutegravir. Calcium and vitamin D supplementation are also essential to improve bone health and reduce the risk of fractures.

Conclusion:

In conclusion, this case highlights the importance of monitoring bone health in patients with HIV on TDF therapy. Regular assessment of bone mineral density and serum vitamin D levels can help detect osteopenia early and prevent further bone loss. Prompt recognition and management of TDF-induced osteopenia, including switching to alternative antiretroviral therapy, supplementation with calcium/vitamin D, physiotherapy and lifestyle modifications are crucial to improving bone health and quality of life in these patients.
