Heavy Metal Intake by Fishes of Different River Locations in Bangladesh: A Comparative Statistical Review

ABSTRACT

Bangladesh is a highly densely populated country and fulfils its maximum protein demands from fish. The observation from this investigation is very alarming that heavy metals polluted the major river water by the growing garment washing, dyeing and textile, fertilizer, cement, tannery, metal, electrochemical, pharmaceutical industries etc. are the main culprits that don't have proper effective effluent treatment plants (ETP). High-value heavy metals in industrial area river fish as chromium (Cr) 164.73 mg/kg in *Heteropneustesfossilis* (stinging catfish) at Buriganga river, Hazaribagh, zinc (Zn) 309.47 mg/kg in *Mastacembelusarmatus* (Bain) fish at Bangshi river, Savar, copper (Cu) 26.33 mg/kg in *Mastacembelusarmatus* (Bain) at Bangshi river, Savar, arsenic (As) 5.64 mg/kg in *Heteropneustesfossilis* (stinging catfish) at Bangshi river, Savar, lead (Pb) 18.16 mg/kg in *Channa punctatus* (Taki) atBuriganga river, Hazaribagh and cadmium (Cd) 2.03 mg/kg in *Heteropneustesfossilis* (stinging catfish) at Buriganga river, Hazaribagh were observed. The two rivers are identified as most contaminated by heavy metals one is Bangshi River, Savar, Gazipur and another is Buriganga River, Hazaribagh. The main reason for the contamination of these two rivers was uncontrolled industrialization around Dhaka and in Hazaribagh, a huge number of tanneries have grown that use a huge quantity of Cr creating a threat to the ecosystem and even a serious health risk for humans. The river water ecosystem is contaminated by heavy metals that intake fish and this contamination expands to the human body and is responsible for various critical diseases.

Keywords: Eco-system, effluent, health effect, heavy metal, point and non-point source, toxicity.

1. Introduction

Heavy metals are generally characterized as metals with elevated densities, atomic weights or atomic numbers [1].Heavy metals and metalloids are inherently non-biodegradable and possess the capacity to adversely impact human health, both by direct and indirect means [1].Environmental contamination has become a global threat and heavy metals are regarded as one of the most significant polluting agents [2].Heavy metal pollution in aquatic ecosystems is a primary apprehension due to the toxicity, permanence, non-biodegradable nature and abundance of these metals in the environment [3]. Also, the accumulation of heavy metals in aquatic habitats poses a severe threat [3-4]. The basic contributors to heavy metal contamination in aquatic habitats are natural processes, urbanization, industrialization and agricultural activities [5]. The expeditious growth of industries, the proliferation of cities and sundry anthropogenic undertakings have led to the extensive dissemination of cadmium (Cd), lead (Pb) and chromium (Cr) in the ecosystem [6].As a developing nation, the heavy metal concentration in the aquatic environment has escalated and intensified concerns in Bangladesh [7-8], in addition to the lethal toxicity, intrinsic persistence, non-biodegradability and accumulative nature of these metals [9].The rivers around Dhaka and Chittagong, namely, the Buriganga, Turag, Shitalakhya, and Karnaphuli, are extensively contaminated with Cd, Pb and Cr [10-13]. The quality of river water can be adversely impacted by industrial discharge and sewage by the addition of heavy metals [14]. In addition, the species of fish from the contaminated river intake heavy metal in a high concentration [14-15].The significant volume of traffic [16] also contributes to a substantial presence of heavy metals and metalloids in the water and soil that result the pollution. Aquatic species such as fish and invertebrates are susceptible to contamination from inadequately treated both point-source (industries) and non-point-source (agriculture) pollutants [17]. For instance, the contamination of surface water, the disposal of agricultural and industrial effluents and the application of chemical fertilizers and pesticides comprise the dominant sources of heavy metal contamination [17].

UNDER PEER REVIEW

On the contrary, fish is usually ingested owing to its lipid, protein, vitamin and mineral constituents and primarily the existence of long-chain omega-3 polyunsaturated fatty acids (PUFAs) [18]. Moreover, alongside long-chain omega-3 PUFAs, researchers have identified numerous other components of fish that are beneficial to human health [19].While certain trace metals are necessary for maintaining human metabolism, they may be toxic when present in excessive concentrations. Moreover, certain metals, namely Cadmium, Lead and Mercury, possess high toxicity [20]. As the concentrations of these metals reach the permissible optimal limit, they progressively mix in water, ultimately sediment into sedimentary strata [21]. Through feeding upon benthic and pelagic species-contaminated water, they accumulate within the bodies of fish, generating differences between their uptake and elimination rates [21-22]. The established maximum tolerance range for Cr is 0.1-1.0 mg/kg by the standards of FAO [24] (Food and Agriculture Organization), WHO (World Health Organization)[25], and MOFL [23] (Ministry of Fisheries and Livestock).The upper limit for Cu consumption in children aged 1.0 – 3.0 years is 1.0 mg/ per day while for adults aged 19.0-70.0, it is set at 10.0 mg per day [26]. The concentration of Pb, as set by FAO [24], is 0.5 mg/kg while the Joint Expert Committee on Food Additives (JECFA) [28] permits up to 3.0 mg/kg. In Bangladesh, the MOFL [23] has set the permissible limit for Pb at 0.3 mg/kg. The FAO/WHO [29] and EU (European Union) [30] have proposed a maximum permissible limit of 100.0 mg/kg and 30.0 mg/kg for Zn in fish and fish products, respectively.The established permissible limit for As is 1.0 mg/kg set by the California Environmental Protection Agency (CEPA) and FAO [24]. On the other hand, the accepted limit set by MOFL [23] in Bangladesh is 5.0 mg/kg. The acceptable limit for Cd 0.1 mg/kg is established by FAO and WHO [25]. Also, the limit for Cd set by MOFL [23] is 0.25 mg/kg. Prolonged exposure to heavy metals and metalloids can result in damage to multiple organs such as the kidneys, liver, lungs, brain and bones [31-32]. The higher concentration of Cr intake in

UNDER PEER REVIEW

food or fish and the most severe instances, it may give rise to pulmonary ailments [33] and inflict damage upon vital organs including the liver, lungs and kidneys [34] and cause cancer. Overconsumption of copper may lead to injury in the liver and kidneys [27]. From this point of view, this review should highlight the adverse effects of heavy metals on human health and the risk of different health issues and contamination of available fish in different regions of rivers in Bangladesh.

2. Material and Method

2.1 Study Area

The location or area selected for this study is two different sites, site 1 is the industrial zone river and Site 2 is the coastal zone river and available fishes of that area river. For example, in Fig.1. shows the taken Dhaka and surrounding Dhaka area river study data for analysis of industrial zone river fishes heavy metal contamination and for coastal zone like as Sundarbans, Noakhali, Chandpur,Chittagong Port, Bhola, Coxes bazar etc. area river fish’s study on heavy metal contamination.

UNDER PEER REVIEW

2.2 Research Sample Collection

We investigate the study data for six (6.0) local fishes as *Heteropneustesfossilis* (stinging catfish), *Tenualosailisha* (Ilish), *Channa punctatus* (Taki), *Trichogasterfasciata* (Kholshe), *Mastacembelusarmatus* (Bain) and *Anabas testudineus* (Koi) fish of Bangladesh and different locations of rivers in Bangladesh like as Upper Meghna river, Chandpur, Bangshi river, Savar, Turag river, Dhaka, Buriganga river, Dhaka, Shitalakha river, Narayanganj, Meghna river Adjacent to Narsingdi, Buriganga river, Hazaribagh Beside tannery, Dhaleshwari river, Tangail, Meghna Estuary river, Noakhali, Meghna Estuary river, Bhola, Chittagong Port, Cox's Bazar, Sundarbans, river in Chandpur and river in Noakhali.

2.3 Sample preparation

Firstly, the fish sample was washed with deionized water and soaked with tissue paper or soft cotton fabric aim is to remove the moisture and then gut and flesh separation and collection in a watch glass for each sample [36]. The identification and analysis of Pb, Cd and Cr required about 20.0 g of samples in cleaned beakers [36]. The samples dried in an oven at 105.0 ^{0}C daylong. From the dry oven, the beaker containing the sample was placed in a muffle covering with a watch glass remaining gap at 150.0 ^{0}C for 1.0 hour and then the temperature raising 200.0 ^{0}C, 300.0 ^{0}C and 400.0 ^{0}C gradually to avoid the loss of the sample and maintaining each temperature for an hour and lastly the temperature raised to 550.0 ^{0}C and kept for 4.0 – 5.0 hours for getting white colour ash and that is free from carbon [36]. After complete ashing, the beaker of the sample was removed from the furnace. After that, 1.0 – 3.0 ml of concentrated nitric acid and distilled water with a ratio of 1:1 is added to the beaker to remove the rest amount of the carbon from the sample and then heated on the hot plate at about 150.0 ^{0}C under the fume hood to remove the fume until dry [36]. The beaker was again taken in the furnace for heating at 550.0 ^{0}C for 2.0 – 3.0 hours after that cooled. The sample was taken in volumetric flux for rinse with distilled water. The flax was shaken well to mix uniformly then it was transferred in a black or

UNDER PEER REVIEW

non-transparent plastic bottle then it was filtered with filter paper and sample-making for heavy metal analysis [36].

For the analysis of Hg and As required relatively low boiling point, about 20.0 g of fish samples were taken in cleaned and dried beakers and then 20.0 ml of concentrated nitric acid and 10.0 ml of concentrated perchloric acid were added to each sample in beakers [36]. The sample in beakers is boiled for digestion on the hot plate at 180.0 - 200.0 ^{0}C covering with a watch glass under a fume hood chamber to almost dryness [36]. The process is repeated until a colourless solution is obtained by evaporating the volatile organic matter after complete decomposition with oxidizing acids. The sample was taken in volumetric flux for rinse with distilled water. The flax is shaken well to mix uniformly then it is transferred in a black or non-transparent plastic bottle then it is filtered with filter paper and sample making for heavy metal analysis [36]. Three replicates are made for each fish sample preparation in both of the above processes. A sample blank is also prepared in both processes following the same procedure as described for quality control [36].

3. Characterization

3.1 Basic Principle ofDetection and Determination of Heavy Metal

Atomic Absorption Spectroscopy (AAS) is a method in Spectro analysis employed for the precise determination of chemical elements by fixing the absorption of optical radiation, specifically light through free atoms in the gaseous state [35]. Block diagram of an atomic absorption spectrometer in Fig. 2. To analyze a sample's atomic components, firstly it must be atomized using flame or electrothermal (graphite tube) atomizers, both of which are commonly used today. The resulting atoms are then exposed to optical radiation which may from a line or continuum radiation source specific to the element in question originate [35]. This radiation is then passed through a monochromator to distinguish it from any extraneous radiation generated by the source and is eventually quantified by a detector [35].

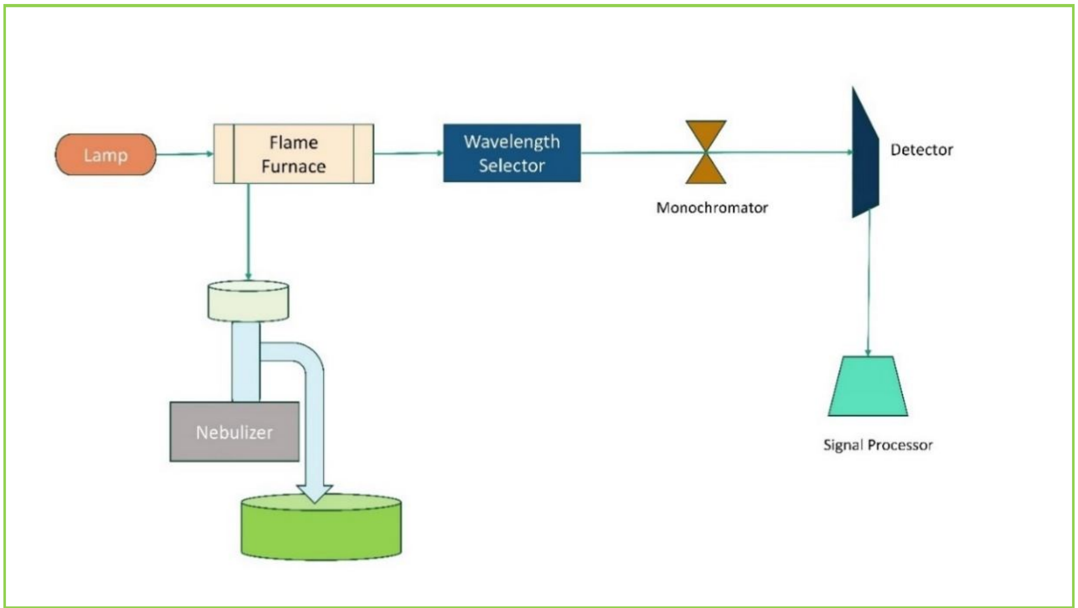

Fig. 2. Block diagram of single-beam instrument AAS [35,37]

For the detection of Pb, Cr and Cd concentrations of samples for both water and fish use the GFAA method by electrothermal AAS (ET AAS) [35-36].The concentration of Hg in the samples is analyzed by utilizing the cold vapour hydride generation technique in AAS [36]. Similarly, the electric hydride vapour generation technique in AAS is applied for the determination of the concentration of As in the samples [36]. A schematic diagram for AAS is shown in Fig. 3.

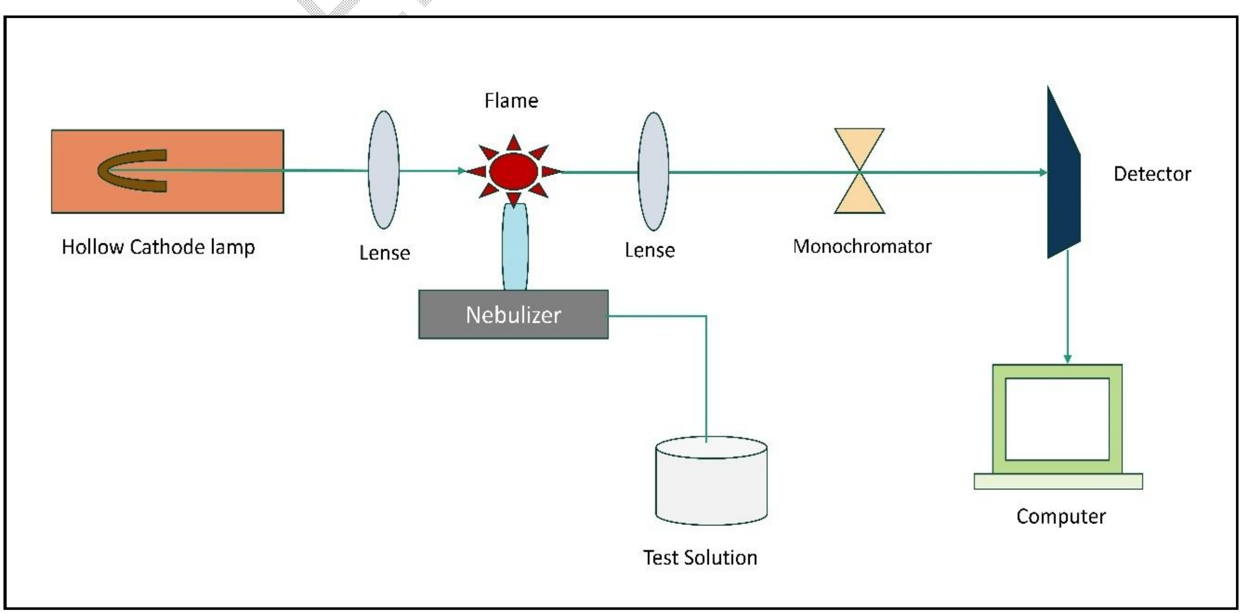

Fig. 3. Operating principals and schematic diagram of AAS

The Method Detection Limit (MDL) for heavy metals such as lead Pb, Cd, Cr, Hg and As to be 4.3411, 0.1986, 1.7963, 0.8071 and 0.0799 μgL^{-1}, correspondingly [36]. On the other hand, for the detection of heavy metal Cr, Ni, Pb, Cu and Zn in river water by AAS and using the 3.0 algorithms like MLP (Multilayer perceptron) for Ni, RBN (Radial basis function network) for Cu and Zn, ANFIS (Adaptive neuro-fuzzy inference system) for Pb [53]. Some conventional techniques are also used for the detection of heavy metals [54] described in Table 1.

4. Result and discussion

4.1 The Heavy Metal Concentration in Fish

Fish contamination with heavy metals poses a serious risk to both human and aquatic life [61]. The initial stage in assessing the scope of contamination in fish is to ascertain the concentration of heavy metals.Human health is at risk due to environmental contamination by heavy metals [59]. The presence of heavy metals Zn, Cd, Pb, Cu, As and Cr in six (6.0) different species of fish is investigated in different rivers of Bangladesh in different regions.

4.1.1 Chromium (Cr)

The main sources of Cr contamination in fish are tannery and poultry waste that is used as a source of fish feed in Bangladesh which significantly increases the contamination in fish [137]. Cr causes acute and chronic toxicity in the living organism. It is carcinogenic and causes cancer [74, 111]. The different locations of the river and six (6.0) fish sample data in which the majority are exceeding the limit of national [68] and international [67] guidelines. The highest value of Cr found in Buriganga River, Hazaribagh [56] beside tannery and for fishes *Heteropneustesfossilis* (stinging catfish) is 164.0 mg/kg and *Channa punctatus* (Taki) is 49.36 mg/kg, another relatively

UNDER PEER REVIEW

high value observed in the River in Noakhali [61] for the fish *Anabas testudineus* (Koi) is 7.86 mg/kg. The maximum tolerance limit for Cr is 0.1-1.0 mg/kg by the standards of FAO [24], WHO [25] and MOFL [23].

4.1.2 Copper (Cu)

Copper is an essential element that benefits sound health by adding iron to form haemoglobin [132]. However limitless intake of Cu may cause liver and kidney damage [133,134]. From the observation the highest intake of Cu 32.49 mg/kg in *Anabas testudineus* (Koi) fish at the River in Noakhali [61]. On the other hand, at the Bangshi River, Savar [60] found the fish *Mastacembelusarmatus* (Bain) intake amount of Cu is 26.33 mg/kg and *Heteropneustesfossilis* (stinging catfish) is 16.4 mg/kg. The upper limit for copper (Cu) consumption in children aged 1.0 – 3.0 years is 1.0 mg per day, while for adults aged 19-70.0, it is set at 10.0 mg per day [26]. The maximum standard limit for Cu is 30.0 mg/kg by FAO [24], WHO [25], FSG [67], India [69], and Malaysia [70] but in Bangladesh [68] the set limit is 5.0 mg/kg.

4.1.3 Arsenic (As)

As contamination in water is difficult to stop because it is caused by natural and man-made sources [111]. It has the risk of cancer and causes skin lesions [74,111]. The recordable value for As obtained in a fish sample of *Heteropneustesfossilis* (stinging catfish) is 5.64 mg/kg at Bangshi River, Savar [60] exceeds the set limit value by MOFL [23] in Bangladesh is 5.0 mg/kg. The established permissible limit for As is 1.0 mg/kg set by the California Environmental Protection Agency (CEPA) and FAO [24].

4.1.4 Zinc (Zn)

Zinc plays an important role in the physiology and metabolic processes of various organisms in the human body but excess concentrations of this element can be poisonous and result in

UNDER PEER REVIEW

Parkinson’s disease [135]. The highest value of Zn from analyzed data obtained in *Mastacembelusarmatus* (Bain) fish is 309.47 mg/kg at Bangshi River, Savar [60] also for *Heteropneustesfossilis* (stinging catfish) is 176.98 mg/kg. On the other hand, at the Buriganga River, Hazaribagh [56] the intake amount of Zn in fishes was 184.46 mg/kg and 186.06 mg/kg respectively for *Channa punctatus* (Taki) and *Heteropneustesfossilis* (stinging catfish). The FAO/WHO [29] and EU (European Union) [30] have proposed a maximum permissible limit is 100.0 mg/kg and 30.0 mg/kg for Zn in fish and fish products, respectively.

4.1.5 Lead (Pb)

Lead is a very toxic element that accumulates in the body and damages the central nervous system. The riskiest relative to children and pregnant women [74,111,115]. Among the analyzed data at Buriganga River, Hazaribagh [56] the two fishes sample *Channa punctatus* (Taki) and *Heteropneustesfossilis* (stinging catfish) intake high amounts of Pb as 18.16 mg/kg and 11.05 mg/kg respectively which observed exceeding the maximum standard value in Bangladesh, the MOFL [23] has set the permissible limit for Pb at 0.3 mg/kg. Also, international organizations and countries set their permissible limit as like FAO [24] set 2.0 mg/kg, WHO [25] 0.5 mg/kg, FDA [28] 1.5 mg/kg, India [69] 0.3 mg/kg, Malaysia [70] o.3 mg/kg, China [71] 3.0 mg/kg respectively.

4.1.6 Cadmium (Cd)

Cadmium is a type of element which creates chronic toxicity even if a trace amount is 1.0 mg/kg in food or fish samples [135]. The highest intake of Cd found in*Heteropneustesfossilis* (stinging catfish) is 2.03 mg/kg at Buriganga River, Hazaribagh [56] which exceeds the limit value of the standard. The acceptable limit for Cd 0.1 mg/kg is established by FAO and WHO [25]. Also, the limit for Cd set by MOFL [23] is 0.25 mg/kg. It is observed that highly industrialized and highly

UNDER PEER REVIEW

urbanized area rivers are highly contaminated by heavy metals that are generated from different industries, sewage, untreated wastewater, and point and non-point sources [9,74,75].

4.2 Water pollution by heavy metal from different sources and intake by fish

Heavy metal contamination is responsible for two distinct sources in water, one is pointing sources and another is non-point sources Fig. 4. [9,74]. The point source contaminates the surface water source like rivers, lakes, cannel and ponds by direct discharge or overflow. Non-point source contaminants pollute surface water by rainwater [73]. The anthropogenic/man-made/artificial sources of water contamination are called heavy metal contamination which is caused by human activity. Heavy metal contamination in water is caused by different industrial activities, Agriculture and domestic sources [75].

REVIEW

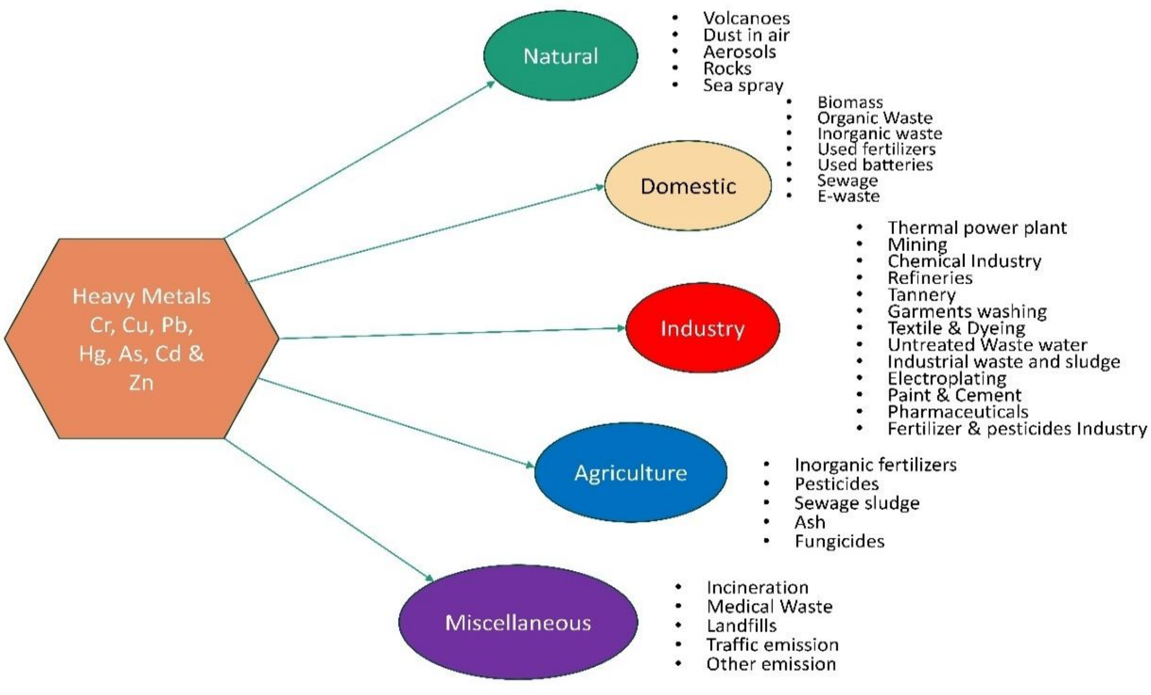

Fig. 4. Sources of heavy metal [73-78]

In the past period, there was a significant increase in the contamination of heavy metals in the surface and groundwater [76].Different industries cause pollution by harmful heavy metals like Cu, Cr, Pb, Zn, As, Hg and Cd in surface water [77]. Due to rapid industrialization, the production of industrial effluent progressively increased [78]. Industries including Ceramic application, plastic manufacturing, tanning, chrome plating, coal mining, metalworking, plastic manufacturing, food production, cement industry and agrochemical wastes are responsible for the pollution of dangerous heavy metals in water sources Fig. 5both surface and groundwater [79].

Industrial discharge effluent is partially treated or untreated wastewater containing heavy metals polluting water which is a significant factor for health issues for both humans and other animals like fish and phytoplankton [80]. The principal constituents of domestic waste are living microorganisms and biodegradable substances [81]. Out of this constituent, domestic waste also provides nitrates, chlorides, nutritive elements, surfactants, lubricants, sewage and noxious metallic compounds [81]. From a previous study in India, the Yamuna River is polluted by domestic waste. The main culprits of domestic contamination are densely populated urban settlements that are polluted by dumping of waste into the river [81].

PEER REVIEW

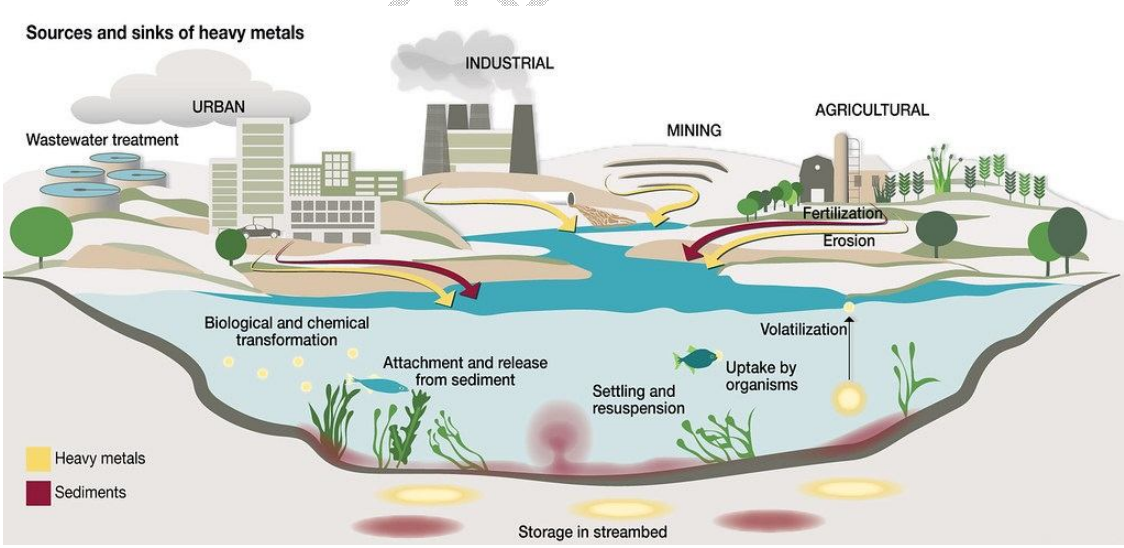

Fig. 5. Water pollution by heavy metals from different sources and contamination of fish and aquatic life [82].

The non-point sources are declared as the pollutants are flow into the river in any way like rain or flood [83]. When run-off the source of the pollutants like fertilizer and pesticides contains heavy metals and passes through by stream from the field [83-84]. Agriculture-related heavy metal pollution of the water is responsible by different sources including fertilizers, herbicides, pesticides and agricultural residues as well as high salts brought about by irrigation water application [85]. The produced agricultural waste in the river basin or neighbouring water resources such as ponds, and lakes is naturally decomposed and leaching poisonous heavy metals and contaminate water [86-87]. Furthermore, the heavy metal contamination attributed to the surface water by the use of agrochemicals. Some heavy metals contained in used fertilizers, pesticides and nutrients are as listed Cd, Pb, Cr, As, Hg, Ni, Cu and Zn [88].The main allocated location for the removal of solid waste is landfilling and it is the reason for extreme ecological degradation and transmissible disease [89-90].

4.3 Toxicity of heavy metals and adverse effect on human health

Almost fifty (50.0) elements are under the classification of heavy metals and they consist of some metalloids, transition metals and lanthanides. Among them, it was studied seventeen (17.0) elements are categorized as extremely harmful, toxic and easier to obtain [91]. The easy availability and release of this extremely harmful heavy metal create a threat to the ecology and the cancer-causing metals found in research [92-93], environment [94-95], and health concerns [96-98]. From the previous research, it was noted approximately 1.6 million children die in a year due to contaminated water [99]. The decline of surface water sources and groundwater quality due to industrial wastes, urban sewage, and agricultural discharge is a concerning issue [74]. The evaluation of groundwater's suitable uses for particular purposes, including irrigation, public water supply, industrial applications and power generation, is significantly reliant on groundwater [100]. Different health risks are shown in Fig. 6. due to water and fish contamination by heavy metals.

UNDER PEER REVIEW

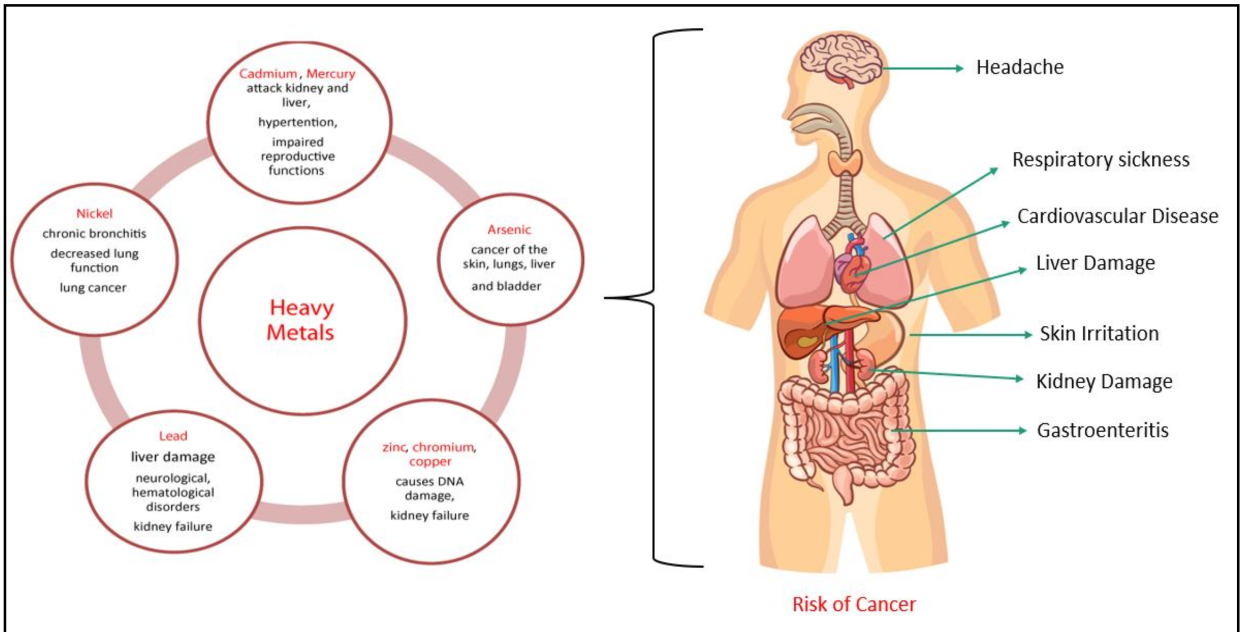

Fig. 6. Water and fish are contaminated by heavy metals and effect on human health [74]**.**

The Caliber of groundwater is gradually but progressively deteriorating on a global scale. Hydrological, physical, chemical and biological aspects are all crucial determinants of groundwater quality [101]. Some trace metals affect the phytochemical and biochemical mechanisms of plants, animals and humans, even other trace metals in small quantities can also be hazardous [102]. The high concentration of trace metals interacts with the human body via three pathways namely inhalation, ingestion and dermal absorption. Humans are contaminating through drinking water, food and dermal contact [103-104].Through food or water, heavy metals when entering the human body initiate diverse processes in the human body. Heavy metals called Cr, Pb, and As obstruct the metabolic pathway or restrict enzymatic activity [130]. Among them, Cr easily passes the cell membrane enters the intermolecular area and reduces due to their lower oxidative stage. For that reason, the reduction process causes oxidative stress within the cell which is also accountable for harming DNA, RNA and proteins [131].The health hazards that are correlated with heavy metal toxicity have been succinctly presented in Table 9 [74, 111].

Table 9. Harmful heavy metals, sources and different health effects.

UNDER PEER REVIEW

Heavy metals	Anthropogenic Source	Health Impacts	References
Cr	Chemical processing, maritime activities, information retention, textile production, hide preparation, dye compounds, timber preservation, metalworking, decolorizing agents, and electrochemical industries.	Causes acute and chronic toxicity in the living organism. It is carcinogenic and causes cancer. Also responsible for Skin rash and ulcers, irritations and bleedings in the nasal cavity, weakened immune system, genetic material mutation, impaired liver and renal functions, teratogenicity, reproductive toxicity, embryotoxicity, mutagenicity and carcinogenicity, dermatitis, septum perforation and untoward reactions. 5. Conclusion

The heavy metal contamination overview is so alarming in industrial areas and uses six (6.0) fish samples from different regions of rivers in Bangladesh. High-value heavy metals in industrial area river fish as chromium (Cr) 164.73 mg/kg in, zinc (Zn) 309.47 mg/kg, copper (Cu) 26.33 mg/kg, arsenic (As) 5.64 mg/kg, lead (Pb) 18.16 mg/kg and cadmium (Cd) 2.03 mg/kg were observed. The obtained value of heavy metals in studied samples for both industrial and urbanized areas was found so high in fish that it exceeded the local and international standards. The contamination of river water and fishes that affects an entire ecosystem. Human health is in big threat regarding heavy metal contamination that is affecting the food chain and groundwater. Different death-causing diseases occur due to this contamination. We have identified the different sources that contaminate the water sources both surface and ground water. This review enables us and enrich our knowledge regarding heavy metal sources and different health concerns. We determined to develop the pathway of proper management and disposal system of heavy metal and proper management system of waste to protect against water pollution.
