

**Editor's Comment:**

The probability of ischaemic heart disease is higher in Indian urban population than the American subcontinent. the nature of the disease is also quite severe and this is one of the factors on which the outcome is decided. This interesting manuscript has brought out the fact that the early reperfusion is essential in STEMI treatment, for better outcome. The authors have also tried to bring out the interesting fact that there are lot of difficulties in reducing the door to balloon time. Socioeconomic and cultural barriers adversely affect the door to balloon time in diverse countries like India. The authors have proposed public awareness campaigns nationwide about common medical emergencies and their solutions may favourably improve treatment in the golden hour.

This case report gives an insight on how an early management of STEMI can be improved in the country. The information would be useful for the clinical physicians, cardiologist and all health care workers.

With due consideration, the decision on the manuscript is Accepted.
