ECONOMICS OF THE INDIVIDUAL CROPS IN MAIZE AND GROUNDNUT CROPPING SYSTEM GROWN UNDER DIFFERENT IRRIGATION SYSTEMS WITH VARIED IRRIGATION AND NITROGEN LEVELS

ABSTRACT

An experiment was conducted to study the effects of irrigation systems, irrigation and N levels on economics of maize and groundnut during 2021-22 and 2022-23 at the College farm, College of Agriculture, Rajendranagar, PJTSAU, and Hyderabad. The experiment consisted 18 treatment combinations (3 irrigation systems as main plot, 3 irrigation levels as sub-plot and 2 nitrogen levels as sub-sub-plot) in a split plot design replicated thrice. The experiment revealed that among irrigation systems, irrigation and N levels in both crops (maize and groundnut) significantly higher gross returns, net returns and BCR were recorded with M₂ (sub surface irrigation system), S₁ (1.2 Epan; IW/CPE) and N₁ (100 per cent RDN). In both crops the interaction between irrigation system and irrigation levels (M x S) revealed significantly higher returns and BCR with sub-surface drip irrigation levels @ 1.2 Epan & 0.9 Epan ratios (M₂S₁ and M₂S₂) followed by surface drip irrigation levels @ 1.2 Epan & 0.9 Epan ratios (M₁S₁ and M₁S₂), surface irrigation @ 1.2 IW/CPE ratio (M₃S₁) whereas surface irrigation @ 0.6 IW/CPE ratio (M₃S₃) resulted in least returns and BCR during both the years. The interaction effects of irrigation systems and N levels (M x N), irrigation and N levels (S x N) were non-significant in groundnut crop whereas significant in maize crop. The M₂N₁ recorded significantly higher mean gross returns (₹. 1,46,852 ha⁻¹), net returns (₹. 90,960 ha⁻¹) and BCR (2.62) whereas M₃N₂ recorded lowest mean gross return (₹. 97,052 ha⁻¹), net return (₹. 45,305 ha⁻¹) and BCR (1.87). Among S x N interaction effects, the S₁N₁ (1.2 Epan; IW/CPE with 100 per cent RDN) resulted in significantly higher gross returns (₹. 1,44,385 ha⁻¹), net returns (₹. 89,256 ha⁻¹) and BCR (2.61) followed by S₂N₁ while S₃N₂ resulted in significantly least returns and BCR. The interaction effects of irrigation systems, irrigation and N levels (M x S x N) was non-significant in groundnut crop while showed a significant impact on economics of maize. The sub-surface irrigation system (M₂) with 1.2 Epan (S₁) and 100 per cent RDN (N₁) recorded significantly higher mean gross returns (₹. 1,58,749 ha⁻¹), net return (₹. 1,10,243 ha⁻¹) and BCR (2.82) followed by M₂S₂N₁ (₹. 1,56,106 ha⁻¹, ₹. 1,14,542 ha⁻¹ and 2.79), M₁S₁N₁ and M₁S₂N₁ while M₃S₃N₂ (surface irrigation system with 0.6 IW/CPE and 75 per cent RDN) recorded least mean gross returns (₹. 65,253 ha⁻¹), net returns (₹. 14,106 ha⁻¹) and BCR (1.28) thus making it the least remunerative among all treatment combinations studied.

Keywords: Maize, groundnut, **Impact** irrigation systems, net returns, gross returns and BCR

1. INTRODUCTION

Groundnut, or peanut, is commonly called the poor man's nut. Today it is an important oilseed and food crop. This plant is native to South America and has never been found uncultivated. The botanical name for groundnut, *Arachis hypogaea* Linn., is derived from two Greek words, *Arachis* meaning a legume and *hypogaea* meaning below ground, referring to the formation of pods in the soil. Groundnut is an upright or prostrate annual plant. It is generally distributed in the tropical, sub-tropical and warm temperate zones. Ethnological studies of the major Indian tribes of South

America document the widespread culture of groundnut and provide indirect evidence for its domestication long before the Spanish Conquest. When the Spaniards returned to Europe they took groundnuts with them. Later traders were responsible for spreading the groundnut to Asia and Africa where it is now is grown between the latitudes 40°N and 40°S

Maize, the fastest growing cash crop, is growing throughout the world and has the highest production among all the cereals. It is preferred staple food for 900 million poor, 120 -140 million poor farm families, and about one-third of all malnourished children globally (Murdia *et al.* 2016). Maize is the third most important food grain following wheat and rice for Indian population and is cultivated over 9.6 million hectare area with an annual production and productivity of 28.7 million tonnes and 3.0 t ha⁻¹

(India Stat, 2023). Similarly groundnut is considered as the most important oilseed crop in India with a cultivated area of 4.8 million hectare with an annual production and productivity of 9.95 million tonnes and 2.06 t ha⁻¹. Both maize and groundnut crops ranks 4th and 1st in acreage but 6th and 2nd in production globally which clearly indicates that the yield potential of maize and groundnut crops are inevitably smaller than productivity of USA (10.7 & 4.3 t ha⁻¹), China (6.3 & 3.9 t ha⁻¹) and Argentine (7.5 & 3.5 t ha⁻¹) because achieving maximum yield potential requires near perfect management of crop and soil factors which are lacking in farm fields in India (Sreekanth *et al.* 2017). **Intercropping maize and peanuts can increase land productivity and yield. Maize is a superior crop that can obtain resources better than peanuts. The improved canopy structure of the intercropped crop population allows the leaves of corn to receive the right amount of sun radiation. However, intercropping peanuts with corn can decrease yield compared to sole peanut production because of long-term exposure to corn shading.**

In Telangana 8.5 million hectare area is gross cropped employing 66.13% of state workers which contributed 15 & 19% in real and nominal terms to the state gross value addition (GVA) in the triennium ending 2021-22 (MOSPI, 2021). Similarly, 36% of the state's land is double cropped, 64.6% farmers are marginal and 23.7% farmers are small. Telangana is rice and cotton centric contributing 52% of state crop value of output (VOO), however the cereal contribution has shrunk from 44% in 2014-15 to 18% in 2019-20 despite the fact that apart from gram, pulses do not appear to be profitable for Telangana farmers as Telangana agricultural households earns about ₹. 4,917 per month as compare to Punjab's crop income of ₹.12,597 per month which indicates that the higher agricultural growth in Telangana has not translated into high income levels for farmers (Saini *et al.*, 2023). On this consideration, there is an imminent need to improve cultural practices like fertilizer application along with proper method of irrigation as water and nutrients are the basic imperative inputs in crop production due to its diverse needs (Sezen *et al.*, 2011) and on this basis micro irrigation along with fertigation provides the scope for maximizing the crop productivity and monetary returns per unit area and input (Jain *et al.*, 2021). Selection of appropriate crops especially when micro irrigation systems are resorted is a critical decision to be made, considering the initial costs involved. The significance of the selection is more paramount under sandy loam soils of Telangana wherein increasing the cropping intensity is more challenging due to its innate lower productivity and low water & nutrient holding capacity nature.

Crop productivity and N uptake were evaluated. The economic return and N use efficiency (NUE) were calculated. Soil inorganic N (N_{min}) was measured after harvest.

The pea-maize double-cropping allowed the saving of N fertilizer without yield penalties. Besides, a pre-crop effect of pea in the maize yield was observed. Regarding the cropping system, pea-maize obtained a higher economic return the first year. Besides, the economic return was higher the first year, due to crop penalties. In general, NUE was greater in 0N, and no differences were observed between fertilized treatments. Soil N_{min} after pea/barley was higher the first year, coincident with a higher productivity.

With productive farmland facing increased pressure from growing population, cereal-legume rotations have been proposed as an effective mean to increase the productivity of nutrient-depleted and low water holding capacity soils in low-external input systems (Buerkert *et al.*, 2001) and to ensure nutritional security. The resource use efficiency, gross and net returns can be increased by fertigation wherein the plants

nutrients are applied with irrigation water, mainly through micro irrigation systems (Jat *et al.*, 2011). Fertigation is relatively a recent innovative method by which fertilizers are applied along with irrigation water through drip system to enhance fertilizer-use efficiency besides increasing the crop yields and monetary returns. Studies shows that drip irrigated maize and groundnut had greater yield, market grade, and gross revenue compared with conventional irrigated regimes (Sorensen and Lamb, 2009). However information on economics for this intensive cropping system is limited. Particularly under different irrigation systems with varied irrigation and nitrogen levels. Therefore, the present experiment on economics in maize- groundnut crop system with varied irrigation system, irrigation levels and nitrogen levels was conducted.

2. MATERIAL AND METHODS

The current experiment was conducted during *rabi* and summer seasons of 2021-22 and 2022-23 at College farm, College of Agriculture, Rajendranagar. The soil of experimental site was sandy clay loam in texture, moderately alkaline in reaction (pH 7.90), low in available nitrogen ($213.58 \text{ kg ha}^{-1}$), moderately high in phosphorus (25.32

kg ha⁻¹) and medium in potassium content (180.54 kg ha⁻¹). The moisture content at field capacity and permanent wilting point were 18.44 and 7.88% respectively. The bulk density was 1.41 Mg cm⁻³. The experiment consisted of three irrigation systems as main plots viz., M₁ - surface drip irrigation system, M₂ - sub-surface drip irrigation system, M₃ - surface irrigation system, three irrigation levels as sub-plot viz., S₁-1.2 Epan; IW/CPE, S₂-0.9 Epan; IW/CPE, S₃-0.6 Epan; IW/CPE and two nitrogen levels as sub-sub-plot viz., N₁-100 per cent RDN, N₂- 75 per cent RDN in split plot design replicated thrice. Maize and groundnut varieties KMNH-4010141 and Leepakshi constituted the experimental material. The gross and net plot sizes were 6.0 m x 4.8 m and 4.8 m x 3.6 m, respectively. A complete drip system was installed by Netafim Irrigation Limited. The water distribution system consisted of a main line and eighteen sub-mains, each having control valve for water regulation. Irrigation water from manifolds flowed into 16 mm dripper lines laid out on the ground surface at 0.60 m apart with spacing of 0.40 m between two inline emitters delivering 2 L hr⁻¹ in surface drip irrigation system while in sub surface irrigation system the dripper lines were laid out 15 cm below the soil surface with the same spacing and specification as in surface drip irrigation system. Control valves were fixed separately to each treatment plot to facilitate controlling the water flow as per treatments. Water meter was fixed at the head control unit to quantify the amount of water delivered in each irrigation treatment. Scheduling of irrigation in M₁ and M₂ were fixed on daily basis for maize and groundnut crops based on daily evaporation data recorded from (USWB open pan Evaporimeter) obtained from the ACRC, ARI, Rajendranagar, Hyderabad. In surface irrigation system (M₃) the sub treatment plots were leveled manually, ridge & furrow and flat-bed land configurations were maintained for maize and groundnut crops during both years of experiment. In maize and groundnut crops the irrigation was scheduled based on climatological approach when CPE reached 50 and 60 mm depth respectively.

Recommended doses of N, P₂O₅ and K₂O were 240:80:80 and 30:40:50 kg ha⁻¹ NPK for maize and groundnut respectively, applied in the form of urea, single super phosphate and sulphate of potassium for maize while urea, single super phosphate and muriate of potash for groundnut. In both surface and sub-surface drip irrigation systems (M₁ and M₂) a comprehensive fertigation schedule was adopted for maize crop which was already developed by PJTSAU based on crop growth stages and their uptake patterns (Table 1) while in groundnut nitrogen was fertigated in the form of urea in four splits at one week interval after proper crop establishment. In surface irrigation system (M₃) for maize crop, 1/3rd N, full dose of P₂O₅ and K₂O were applied as basal while remaining 2/3rd N was applied in two splits; 1/3rd N at knee height stage and remaining 1/3rd at tasseling depending on irrigation levels in both years whereas in groundnut crop under surface irrigation system, 2/3rd N, full dose of P₂O₅ and K₂O were applied as basal dose while remaining 1/3rd N was applied at 30 DAS.

Economic Impact

China and India together are the world's leading groundnut producers accounting for nearly 60 percent of the production and 52 percent of the crop area. India cultivates about 7.74 million hectares and produces 7.61 million tonnes of groundnut with the productivity level of 991.8 kg ha⁻¹. South Africa is the major producer in Africa, while in Latin America almost one half of the total groundnut produced in that region may be credited to Argentina. Among GROUNDNUT: Post-harvest Operations Page 4 the developing countries Egypt has the highest productivity and capacity to produce groundnuts (Table 1). In most of the developing countries, the productivity levels are lower than in the United States of America, mainly due to a number of production constraints such as i.) the cultivation of the crop on marginal lands under rainfed

conditions; ii.) Occurrence of frequent drought stress due to vagaries of monsoon; and iii.) higher incidence of disease and pest attacks; iv.) low input-use and v.) factors related to socio-economic infrastructure.

Table 1. Fertigation schedule for *rabi* maize.

Crop growth stage	Nutrient dose (kg ha ⁻¹ day ⁻¹)	
	Urea	SOP
After sowing; 20 days (10 – 30 DAS)	3.22	1.48
Grand growth period; 25 days (31-55 DAS)	8.66	2.48
Reproductive stage; 20 days (56 – 75 DAS)	8.16	1.98

Kernel development stage; 25 days (76 – 90 DAS)	4.95	1.98
---	------	------

3. RESULTS AND DISCUSSION

Effects of irrigation systems, irrigation and N levels on economics in maize and groundnut.

Effects of irrigation systems

A scrutiny of data (Table 2 and 3) indicated that the mean gross returns (₹. 1,40,507 and 1,91,409 ha⁻¹), net returns (₹. 85,006 and 1,39,683 ha⁻¹) and BCR (2.53 and 3.70) in sub-surface drip irrigation system (M₂) were significantly highest in both maize and groundnut crops when compared to surface drip irrigation (M₁) and surface irrigation systems (M₃) while the returns and BCR under M₃ remained significantly inferior to M₁ and M₂ in both crops during both the seasons and in means. In maize crop the M₂ recorded 13.12% & 40.94%, 23.1% & 78.7%, 12.4% & 32.5% increased mean gross returns, net returns and BCR when compared to M₁ and M₃ (Table 2) while in groundnut crop with same irrigation system (M₂) an increased (8.8% & 47.3%, 12.1% & 71.2% and 8.1% & 37.9%) mean gross returns, net returns and BCR was recorded over two other irrigation systems (M₁ and M₃) (Table 3). The higher returns and BCR in drip irrigation systems could be attributed to higher economic yields, lesser cost of cultivation and efficient use of fertilizers. Current results are also in similarity with Sivanappan, (1978) who worked out the economics of drip irrigation and reported that drip irrigation gave an additional amount of ₹. 10,000 year⁻¹ on a small farm where the available water was not sufficient to irrigate by surface method. Pawar *et al.* (2015) also reported that drip irrigation system resulted in 27% higher gross returns (₹. 1,13,480 ha⁻¹) over surface irrigation system (₹. 89,302 ha⁻¹). Joshi *et al.* (2015) also observed higher net returns and BCR in drip irrigation over surface irrigation system. These findings are also supported by Shruti and Aladakatti (2017) who observed furrow method of irrigation recorded least net returns (₹. 58,317 ha⁻¹) as well as lowest BCR (2.18) when compared with drip irrigation system.

Effects of irrigation levels

Data presented in Table 2 and 3 indicated that, among the three irrigation levels, 1.2 Epan; IW/CPE (S₁) recorded significantly higher gross returns, net returns and BCR over other two irrigation levels (S₂ and S₃) in both crops (maize and groundnut) during both the seasons and in mean while the lowest returns and BCR was recorded under irrigation scheduled at 0.6 Epan; IW/CPE (S₃). In maize crop an overall 5.83% & 44.89%, 9.31% & 100.75%, 4.96% & 42.95% and in groundnut crop 3.64% & 53.3%, 4.7% & 88.2%, 2.7% & 50.9% increased mean gross, net returns and BCR was witnessed with S₁ over two other irrigation levels (S₂ & S₃) (Table 2 and 3). The reason for higher returns and BCR with S₁ (1.2 Epan; IW/CPE) could be attributed to favorable soil moisture conditions maintained throughout the crop growth period which enhanced the photosynthetic rate, biomass accumulation and partition into economic parts. The lowest returns and BCR under S₃ (0.6 Epan; IW/CPE) might be due to the fact that moisture was not sufficient for crop to absorb the nutrients efficiently, as water is medium for nutrient absorption, which resulted in reduced leaf area, photosynthesis, biomass production and consequently lesser economic yield. Similar findings were also reported by Shivakumar *et al.* (2011), Sharan (2012) and Bibe *et al.* (2017).

Effects of Nitrogen levels

Among N levels significantly higher mean gross returns (₹. 1,27,180 and ₹.1,72,190 ha⁻¹), net returns (₹. 72,524 and ₹.1,21,650 ha⁻¹) and BCR (2.31 and 3.39) was observed with N₁ (100 per cent RDN) in both maize and groundnut crops and hence proved economically profitable over N₂ (75 per cent RDN) which resulted in comparatively lesser mean gross returns (₹. 1,15,756 and ₹.1,59,336 ha⁻¹), net returns (₹. 61,879 and ₹. 1,08,892 ha⁻¹) and BCR (2.14 and 3.14) (Table 2 and 3). The mean% increase with N₁ over N₂ was 9.87%, 17.2% & 8.23% in maize and 8.1%, 11.7% and 7.9% in groundnut crop in term of mean gross returns, net returns and BCR. The application of 100 per cent RDN (N₁) was in accordance with the plants nutrient needs resulting in higher economics yields. The higher returns and BCR in N₁ is attributed to higher availability of N in the soil solution, which resulted in higher absorption and improved crop growth and ultimately final yield, which resulted in higher economic returns. Similarly, Fanish *et al.* (2011) and Sharan (2012) also reported higher economic returns under increased levels of fertilizers.

Interaction effects

The interaction effects of different treatments on economics of maize and groundnut are depicted in (Table 4, 5, 6 and 7). The interaction between irrigation systems and irrigation levels (M x S), irrigation systems and N levels (M x N), irrigation levels and N levels (S x N) and the interaction effect within irrigation systems, irrigation levels and N levels (M x S x N) was significant in maize crop while in groundnut all the interactions were non-significant except for the interaction between irrigation systems and irrigation levels (M x S) during both the years.

Interaction between different irrigation systems and irrigation levels

Whenever maize and groundnut crops are grown with limited water specific methodologies/systems shall be adopted to ensure maximum returns. In current study in case of interaction between irrigation system and irrigation levels (M x S), the sub-surface drip irrigation levels with either 1.2 or 0.9 Epan (M₂S₁ and M₂S₂) resulted in higher gross returns, net returns and BCR followed by surface drip irrigation levels with 1.2 or 0.9 Epan (M₁S₁ and M₁S₂) over surface flood irrigation with 1.2, 0.9 or 0.6 IW/CPE ratios (M₃S₁, M₃S₂ or M₃S₃) (Table 4). The mean gross returns (₹. 1,51,594 and ₹. 2,13,539 ha⁻¹), net returns (₹. 95,760 and ₹. 1,61,479 ha⁻¹) & BCR (2.71 and 4.10) were significantly higher in sub-surface drip irrigation system with 1.2 Epan (S₁) and decreased in order: M₂S₂ > M₁S₁ > M₁S₂ > M₃S₁ > M₂S₃ > M₃S₂ > M₁S₃ > M₃S₃ in both maize and groundnut crops. An overall 6.3, 15.2, 53.8, 1.4, 25.7, 25.6, 36.4 & 125.5% increased mean gross returns and 10.0, 25.5, 19.0, 2.04, 46.3, 41.2, 61.9 & 510.0% increased mean net returns were observed in maize crop whereas in groundnut crop an overall 5.03, 6.4, 72.5, 3.7, 37.9, 39.4, 48.9 & 129.1 % increased mean gross returns and 6.5, 8.1, 121.9, 4.8, 56.1, 55.1, 69.7 & 255.5% increased mean net returns were recorded with M₂S₁ over M₁S₁, M₁S₂, M₁S₃, M₂S₂, M₂S₃, M₃S₁, M₃S₂ and M₃S₃ respectively. Similarly, M₂S₂ registered 4.8, 13.6, 51.6, 23.9, 23.7, 34.4 and 122.2% increased mean gross returns and 7.8, 23.0, 14.5, 43.4, 38.3, 58.7 and 497.7% increased net returns in maize and 1.3, 2.6, 66.3, 33.0, 34.4, 43.6 & 120.9% increased mean gross returns and 1.7, 3.2, 111.8, 49.0, 48.0, 61.9 & 239.3 % increased net returns in groundnut over M₁S₁, M₁S₂, M₁S₃, M₂S₃, M₃S₁, M₃S₂ and M₃S₃ respectively. The maximum returns and BCR returns in sub-surface drip irrigation system with 1.2 and 0.9 Epan is because of maximum economic yield under same irrigation system and levels. These findings acquire reasonable support from Aladakatti *et al.* (2012) who reported better monetary returns (₹. 34,025 ha⁻¹) and BCR

(1.93) under drip irrigation at 1.0 Epan over surface irrigation system (₹. 29,556 ha⁻¹ and 1.79).

Interaction between different irrigation system and N levels

The interaction effects of irrigation systems and N levels were non-significant in groundnut crop however in maize crop a significant interaction was observed. Across irrigation systems and N levels, the M₂N₁ had significantly higher mean gross returns (₹. 1,46,852 ha⁻¹), net returns (₹. 90,960 ha⁻¹) and BCR (2.62) whereas M₃N₂ recorded lowermost mean gross returns (₹. 97,052 ha⁻¹), net returns (₹. 45,305 ha⁻¹) and BCR (1.87) (Table 5). An overall 10.9, 26.5, 9.45, 43.5 and 51.3% increased mean gross returns and 18.4, 48.4, 15.1, 82.6 and 100.7% mean net returns was observed with M₂N₁ over M₁N₁, M₁N₂, M₂N₂, M₃N₁ and M₃N₂ respectively while M₂N₂ registered 1.3, 15.6, 31.1 and 38.2% increased mean gross returns and 2.9, 29.0, 58.7 and 74.5% increased net returns over M₁N₁, M₁N₂, M₃N₁ and M₃N₂ respectively. Similar results were also reported by Selvakumar, (2006) who observed that drip irrigation at 1.0 Epan recorded an additional net returns (₹. 1,23,679) and BCR (3:30) in chilli followed by 0.8 Epan with 100% RDF registering an additional net return of (₹. 1,19,488) and BCR over surface irrigation system. These results findings are in further accordance to the findings of Senthilkumar (2000), Ramaprabha Nalini (1999) in groundnut and Suresh Kumar (2000) in capsicum under drip irrigation system.

Interaction between different irrigation levels and N levels

The interaction effects of irrigation and N levels were non-significant in groundnut crop however in maize crop the interaction effects between irrigation levels and N levels showed that S₁N₁ (1.2 Epan; IW/CPE with 100 per cent RDN) resulted in significantly higher gross returns (₹. 1,44,385 ha⁻¹), net returns (₹. 89,256 ha⁻¹) and BCR (2.61) followed by S₂N₁ which obtained ₹. 1,38,194 ha⁻¹ gross returns, ₹. 83,564 ha⁻¹ net returns and 2.52 BCR (Table 6). The S₁N₁ registered 9.2, 4.5, 17.2, 45.9 & 75.1% increased mean gross returns and 14.7, 6.8, 28.8, 99.5 & 131.9% increased mean net returns over S₁N₂, S₂N₁, S₂N₂, S₃N₁ and S₃N₂ respectively while S₂N₁ registered 4.5, 12.2, 39.6 & 50.3% increased mean gross returns and 7.4, 20.6, 86.7 & 117.1% increased net returns over S₁N₂, S₂N₂, S₃N₁ and S₃N₂ respectively. Similar results were also observed by Sharan (2012) who recorded significantly higher net returns and BCR with drip irrigation level with 1.2 Epan (₹. 57,266 ha⁻¹ and 2.6) followed by 1.0 Epan (₹. 54,331 ha⁻¹ and 2.6) and 0.8 Epan (₹.39655 ha⁻¹ and 2.2) and lowest with surface irrigation level with 1.0 IW/CPE. (₹.19489 ha⁻¹ and 1.5). These findings are in further accordance to the findings of Vishwanatha *et al.* (2000) and Ramah *et al.* (2010).

Interaction between different irrigation systems, irrigation levels and N levels

The interaction effects of irrigation systems (M), irrigation levels (S) and N levels (N) showed a significant impact on economics of maize and revealed that sub-surface irrigation system (M₂) with 1.2 Epan (S₁) and 100 per cent RDN (N₁) recorded significantly higher mean gross returns (₹. 1,58,749 ha⁻¹), net returns (₹. 1,10,243 ha⁻¹) and BCR (2.82) followed by M₂S₂N₁ which resulted in ₹. 1,56,106 ha⁻¹, ₹. 1,14,542 ha⁻¹ and 2.79 mean gross returns, net returns and BCR. In later treatments M₁S₁N₁ (surface drip irrigation system with 1.2 Epan and 100 per cent RDN) and M₁S₂N₁ (surface drip irrigation system with 0.9 Epan and 100 per cent RDN) resulted in comparatively higher gross returns (₹. 1,49,705 and 1,45,378 ha⁻¹), net returns (₹. 93,820 and 89,792 ha⁻¹) and BCR (2.68 and 2.61), however M₁S₂N₁ remained statistically at par with M₂S₁N₂ (sub-surface drip irrigation system with 1.2 Epan and 75 per cent

RDN) during both the years (2021-22 and 2022-23) whereas the surface irrigation system with 0.6 IW/CPE and 75 per cent RDN ($M_3S_3N_2$) recorded least gross returns (₹. 65,253 ha^{-1}), net returns (₹. 14,106 ha^{-1}) and BCR (1.28) thus making it the least remunerative among all treatment combinations studied (Table 7). Higher gross returns, net returns and BCR in current study were due to higher crop yields, efficient use of fertilizers & irrigation water under sub-surface irrigation system (M_2). These findings are also supported by Shruti and Aladakatti (2017) who observed higher net returns (₹. 134262 ha^{-1}) and improved BCR (3.25) under drip fertigation combination of 1.0 Epan with 100 per cent RDNK over other treatment combinations such as 1.0 Epan with 75 per cent RDNK.

4. CONCLUSION

On the basis of the results obtained in the present investigation it can be concluded that among different irrigation systems with varied irrigation and N levels, the implementation of sub-surface drip irrigation system, 1.2 & 0.9 Epan ratios and 100 per cent RDN could result in significantly higher mean gross returns, net returns and BCR in both maize and groundnut crops while satisfactory economics returns couldn't be achieved with surface irrigation system with 0.9 and 0.6 IW/CPE ratios and 75 per cent RDN in both crops.

UNDER PEER REVIEW
