

Cecal Volvulus: Etiology Uncommon of intestinal occlusion Acute Case Report

ABSTRACT

Caecum volvulus is, in frequency, the second part of the colon concerned by volvulus after the sigmoid and before the transverse colon. This pathology occurs in cecums with abnormal mobility. The mechanism of volvulus can be summarized in 2 mechanisms either by torsion or tilting. The clinical picture is that of an acute intestinal occlusion by strangulation. The abdomen without preparation (ASP) and the abdominal CT are the radiological examinations of first choice for the diagnosis. It is a surgical emergency, the conduct of which is to make a resection of the cecum and the terminal ileum. We report the case of a cecal volvulus admitted to the emergency room with an acute intestinal obstruction, the diagnosis was confirmed by an abdomino-pelvic CT scan and the treatment consisted in an ileo-CAECAL resection with immediate restoration of continuity. Immediate restoration of continuity, the postoperative follow-up was simple.

1. INTRODUCTION

The first description of cecal volvulus was made by Rokitansky in 1837[1]. The volvulus of the cecum is an axial torsion of the cecum, involving the terminal ileum due to abnormal fixation of the cecum [2]. It is responsible for 25-40% of all colonic volvuli in adults. It represents the second most frequently affected part of the colon second most frequently affected by volvulus after the sigmoid [4]. The clinical signs are of a similar intestinal obstruction and they are not specific to cecal volvulus, and it is difficult to differentiate cecal volvulus from other forms of intestinal obstruction [3]. The diagnosis may be delayed. Acute caecal volvulus may progress to caecal gangrene with necrosis and then to perforation leading to acute peritonitis. Abdominal radiography and abdominal CT are the essential radiological procedures for the diagnosis of volvulus of the cecum [6]. The only effective treatment for cecal volvulus is surgical resection [5].

2. CASE PRESENTATION

He is a 38 year old patient followed for chronic dermatitis under corticotherapy were admitted to the emergency room for occlusive syndrome with a symptomatology evolving five days before days before the consultation with clinical examination: conscious patient stable on the hemodynamic and respiratory plan. The examination noted a distended abdomen, hypertympanic, the hernial orifices were free and the rectal ampulla was empty. The

biological work-up revealed a hyperleukocytosis with predominantly PNN at 15 000 elements/mm³, CRP was elevated to 150, renal function was normal unprepared abdomen in the standing position, which revealed a hydroaerobic level of the greaves and abdominal CT which showed a colonic occlusion on volvulus of the colon with collapse of left and right colonic frame with highlighting of an aspect of whirl sign at the level of the right flank (Figure 1, Figure 2).

3. DISCUSSION

Caecal volvulus is a rarely diagnosed clinical situation for intestinal obstruction [7] and an uncommon etiology of intestinal obstruction [7]. It is responsible for about 1 to 1.5% of all intestinal obstructions, while 20 to 40% of all colonic volvulus. Its incidence is 2.8-7.1 cases per million population per year [4].

The volvulus of the cecum is a torsion of the right colon around its mesenteric axis which is only possible if the proximal colon is mobile or congenital anomalies in which the right colon does not fuse properly with the lateral peritoneum [9]. Excessive mobility of the cecum is due to an incomplete embryological rotation of the intestine or to a defect in the attachment of the ascending colon to the posterior parietal peritoneum [14,15].

Caecal volvulus may occur as a result of adhesions due to abdominal surgery, chronic constipation, pregnancy, or prolonged immobility [11].

Two types of volvulus have been described: either by a rotation of the colon around its axis around its axis, with the cecum remaining in the right lower abdominal or by a tilting of the cecum associated with a rotation of the rotation of the colon which is then placed in the left upper abdominal quadrant of the abdomen [12,16,17]. The diagnosis of cecal volvulus is difficult because the clinical signs are not specific and the intensity of the intensity of the pain is extremely variable [15].

Cugnenc et al. reported in a series a mean age of onset of cecal volvulus of 61.8 years and no gender-related predisposition was established [10].

The Mobile caecum syndrome has been reported to occur in nearly 50% of patients before the onset of acute volvulus [13].

Typically, patients present with generalized abdominal pain or predominantly lower quadrant abdominal pain with abdominal distension, and pain resolution after the passage of flatus. The physical findings in patients during symptomatic episodes may include high pitched bowel sounds and right lower quadrant abdominal tenderness. However, these abnormal physical findings generally disappear as the patients' symptoms resolve [18].

In the acute volvulus stage, the patient typically presents with signs of acute bowel obstruction and it is difficult to differentiate caecal volvulus from other forms of small bowel obstruction. A tender and dilated cecum may be palpable in the patient with low BMI, and may help to differentiate cecal volvulus from other forms of bowel obstruction [19].

In case of lack of diagnosis or delay in management, acute cecal volvulus may evolve into intestinal gangrene and then perforation leading to acute stercoral peritonitis [19].

In the advanced stage, patients typically present with generalized and severe abdominal pain, peritoneal irritation disturbances of consciousness and hemodynamic instability [20].

The unprepared abdominal film can be useful for diagnosis, but its sensitivity is diagnosis but its sensitivity is generally low [12] with three typical signs present: dilatation of the cecum; a single hydroaerobic level in the right lower quadrant; and absence of gas in the right colon.

However, up to 30% of patients do not have these radiographic features [21]. Barium enema was used to confirm cecal volvulus. confirmation of cecal volvulus, with a reported diagnostic accuracy of 88% for the acute. It has occasional success in reducing volvulus [18]. It also allows visualization of the distal colon for exclusion of a coexisting anomaly that may have contributed to the formation of the cecal volvulus. Barium enema is not recommended for evaluation of patients with suspected perforation and gangrene [22,23].

CT scan replaced barium enema as the preferred imaging modality for the diagnosis of acute cecal volvulus [6]. The abdominal CT scan is a powerful diagnostic tool. diagnosis. It allows the diagnosis of an associated complication such as ischemia or perforation [16].

The three pathoneumonic CT signs associated with acute cecal volvulus are: "whirl signs" , "coffee bean" and "bird beak"; In the setting of acute cecal volvulus, the whirl is composed of spiralled loop of collapsed caecum, with low attenuating fatty mesentery and engorged mesenteric vessels. Visualization of a gas filled appendix is also a CT scan sign associated with cecal volvulus. The CT scan may show signs of intestinal necrosis or ischemia, which manifest as submucosal edema, diminished or non enhancement of intestinal wall, pneumatosis intestinalis or signs of intestinal perforation such as pneumoperitoneum [6].

Several studies have reported successful colonoscopic reduction of cecal volvulus. The success rate of colonoscopic reduction of cecal volvulus is only 30% with the risk of colonic perforation colonoscopy is not recommended for the treatment of cecal volvulus. [24]

It is generally accepted that the only effective treatment for cecal volvulus is surgery.

Endoscopic detorsion is feasible in the absence of severe ischemia but carries a non-negligible risk of perforation [8]. Treatment has three goals: to remove the obstacle by detorsion, if possible, to treat progressive complications and to prevent recurrence [25]. It remains a controversial subject. Right hemicolectomy with primary anastomosis is recommended by several teams even in the absence of colonic necrosis because it eliminates the risk of recurrence [26-27]. Caecostomy is effective for the prevention of recurrence but carries a high risk of wall infection and exposes the risk of digestive fistula requiring a closure procedure

Laparoscopic procedures are being increasingly used to manage cecal volvulus. Several reports of laparoscopic treatment of cecal volvulus were

published [5] and infectious complications are less frequent with caecopexy but recurrences are more frequent [2].

4. CONCLUSION

The variability of the topography of the ileocecal region and its peritoneal attachments is important. Caecal volvulus should be considered in patients with acute abdominal pain, especially when there are suggestive radiological signs. The diagnosis is most often delayed due to non-specific clinical signs. A rapid and adapted management is necessary to decrease the risk of morbidity and mortality.
